UNIVERSITY COLLEGE OF MEDICINE LIBRARY

LOST IN A MAZE OF BEWILDERING THOUGHTS

'STELAZINE' HELPS FIND THE WAY BACK

The schizophrenic patient is often lost in a maze of bewildering thoughts, confusing voices and frightening anxiety. For such patients, 'Stelazine' provides effective control of these and other psychotic symptoms.

And 'Stelazine' can help patients participate in yo' ...peutic programs. Also important, convenient b.i.d. 'Stelazine' usual' ...s not cause excessive sedation.

After 18 years of extensive research and clinical experience, no other antipsychotic agent has demonstrated significantly greater overall effectiveness and significantly fewer side effects than 'Stelazine'. These facts make 'Stelazine' a first choice for therapy.

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only), 10 mg./ml.

THE USE OF ALTERNATIVE MODES FOR COMMUNICATION IN PSYCHOTHERAPY
The Computer, The Book, The Telephone, The Television, The Tape Recorder

By **David Lester,** *Richard Stockton State College, Pomona, New Jersey.* This book surveys the assorted communication alternatives that have been used in psychotherapy and counseling, and presents a thoughtful analysis of the ramifications these new modes will have on the understanding of the nature of psychotherapy and the reasons for its success.

Each chapter is a self-contained review of the literature pertinent to a specific alternative mode of communication and includes a discussion of the actual and potential uses for that particular mode in psychotherapy and counseling.

- *The telephone* is examined with regard to its application in crisis intervention agencies and its role in psychotherapy.
- *The television* is studied for its use in long distance psychiatric evaluations and as a means for patients to make videotaped monologues.
- *The computer's* usefulness in vocational counseling, administering psychological tests and simple structured interviews is examined.
- *The tape recorder* is discussed with regard to its uses in the administration of psychological tests, its potential as a means for motivating patients, and its applications to behavior modification procedures.
- *The printed word* is scrutinized for its use in bibliotherapy, its helpfulness to deaf and mute psychotherapists and patients, its applications in situations such as advice columns, and its role in Morita therapy and poetry therapy.

In each of these chapters, the unique qualities which the different communication modes bring to the psychotherapeutic situation are also discussed and analyzed. The implications for research are discussed for their relevance to the total understanding of the psychotherapeutic process. *'77, 120 pp., $10.50*

BEHAVIOR THERAPY IN CLINICAL PRACTICE: Decision Making, Procedure and Outcome *by* **Ernest G. Poser,** *McGill Univ., Montreal, Quebec, Canada. Foreword by* **H. J. Eysenck.** A clinical psychologist has developed this material to acquaint mental health professionals with the practical applications of social conditioning principles. Divided into four parts, the text explores specific fears, physical expressions of social withdrawal, socially disapproved behavior, and current problems in behavior modification. Fundamental theories common to all strategies are examined and a sequential approach to selection, observation, treatment and follow-up is outlined. Specific case studies are included to illustrate considerations in selecting proper treatment. *'77, 204 pp., 4 il., 1 table, $13.50*

GROUP COUNSELING AND GROUP PSYCHOTHERAPY WITH REHABILITATION CLIENTS *edited by* **Milton Seligman,** *Univ. of Pittsburgh, Pittsburgh, Pennsylvania. (18 Contributors)* The latest and most authoritative information on theory, research and specialized clinical skills is provided. Group work is discussed in relation to drug and alcohol abusers, the disadvantaged, stroke patients, the physically disabled, those with sensory impairments, the mentally retarded, the terminally ill, and public offenders. Topics include the peer self-help phenomenon, funding priorities, current trends in graduate training programs and processes that characterize the conduct of most groups. *'77, 352 pp., 1 il., 7 tables, cloth-$16.50, paper-$12.75*

BASIC PRINCIPLES OF LONG-TERM PATIENT CARE: Developing a Therapeutic Community *by* **Charles H. Kramer** *and* **Jeannette R. Kramer,** *Family Institute of Chicago, Chicago.* A conceptual framework for developing a therapeutic community which combines the understanding of institutional and family systems with traditional medical and nursing care is provided in this book. The first part of this book develops the theory of the psychosocial system after describing the setting. The second section deals with the transition from theory to practice and the employment of the basic principles as they have evolved. *'76, 380 pp., 1 il., 21 tables, $19.75*

REFLEX EPILEPSY, BEHAVIORAL THERAPY AND CONDITIONAL REFLEXES *by* **Francis M. Forster,** *Univ. of Wisconsin, Madison.* The first portion of this singularly comprehensive text deals with the various causes of the condition including visual and auditory stimuli; higher cognitive functions such as reading, language and decision-making; somatosensory stimulation; and eating and movement. Each of these causes is examined closely in a separate chapter. The latter half of the book considers such topics as classification and differential diagnosis, and the methods, principles of application, and role of medication in treatment. *'77, 328 pp., 87 il., 22 tables, $22.75*

CLINICAL USE OF PSYCHOTHERAPEUTIC DRUGS (5th Ptg.) *by* **Leo E. Hollister,** *Stanford Univ. School of Medicine, Palo Alto, California.* Written for practicing physicians, psychiatrists and students, this book covers drug use in the treatment of emotional disorders in both adults and children. Each class of drugs is considered in relation to the chemical and pharmacological differences among its members, pharmacological properties and pharmacokinetics as these relate to their clinical use, specific clinical indications, general principles of use, use in combination with other drugs, and their side effects and toxicology. *'77, 200 pp., 11 il., 13 tables, $8.95*

MUSIC AND THE BRAIN: Studies in the Neurology of Music *edited by* **Macdonald Critchley,** *National Hospital for Nervous Diseases, and* **R. A. Henson,** *The London Hospital, both of London, England, Foreword by* **Sir Michael Tippett.** *(22 Contributors)* This book deals with neurological aspects of musical experience. The first part is devoted to such topics as hearing, genetics, movement, the nervous control of voice production, psychology of musical talent, musical memory, synesthesia, and brain anatomy and physiology as related to music. The second section contains contributions on musicogenic epilepsy, mental illness in composers, neurological illness in performing musicians, deafness, occupational palsies, and music therapy. *'77, 476 pp., 59 il., 6 tables, $29.50*

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, and are not being considered for publication elsewhere. Papers with multiple authors are reviewed with the assumption that all authors have approved them.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. All submissions must be accompanied by a cover letter *signed by all authors* and using the following wording:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. The cover letter in such cases should contain the following wording and should be signed by all authors:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 2–3 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by the appropriate cover letter, including the copyright transfer statement, will not be reviewed until such a statement is received.

Authors will be notified as soon as possible of the receipt of their paper; at this time, the paper will be assigned a number that must be included in all further correspondence. It is imperative that authors of papers under consideration notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in *final form*, i.e., are ready for review. Authors must *not* submit their papers before the meeting if they expect any substant... due to discussion at the meeting, further researc... papers are subject to the same peer review cri... submissions, and not all papers can be publish... *nal*. Submitted p... stantially exceed the stated maximum length ... ures will be returned to the author unreviewe...

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular or Brief Communication length (a "prompt publication policy" is automatically in effect for Clinical and Research Reports). These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality, and authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed *double-spaced* throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review or listing may be sent directly to the Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Book reviews are usually solicited by the editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer. Reviews are usually less than 500 words long, seldom contain references, and will be edited.

TYPING AND ARRANGING THE PAPER

All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) *nonerasable* bond paper. All parts of the manuscript, including case reports, quotations, references, and tables, must be double-spaced throughout. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Please include degrees (other than honorary or undergraduate) after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. The authors' position titles and affiliations should be given in a paragraph using complete sentences. A full address is necessary only for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications (no précis is used in the Clinical and Research Reports section). The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided; overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material; a complete review of the literature is rarely desirable. *Accuracy of citation is the author's responsibility.* References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do *not* arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below and on the next page, double-spaced *throughout* (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26

2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information available in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

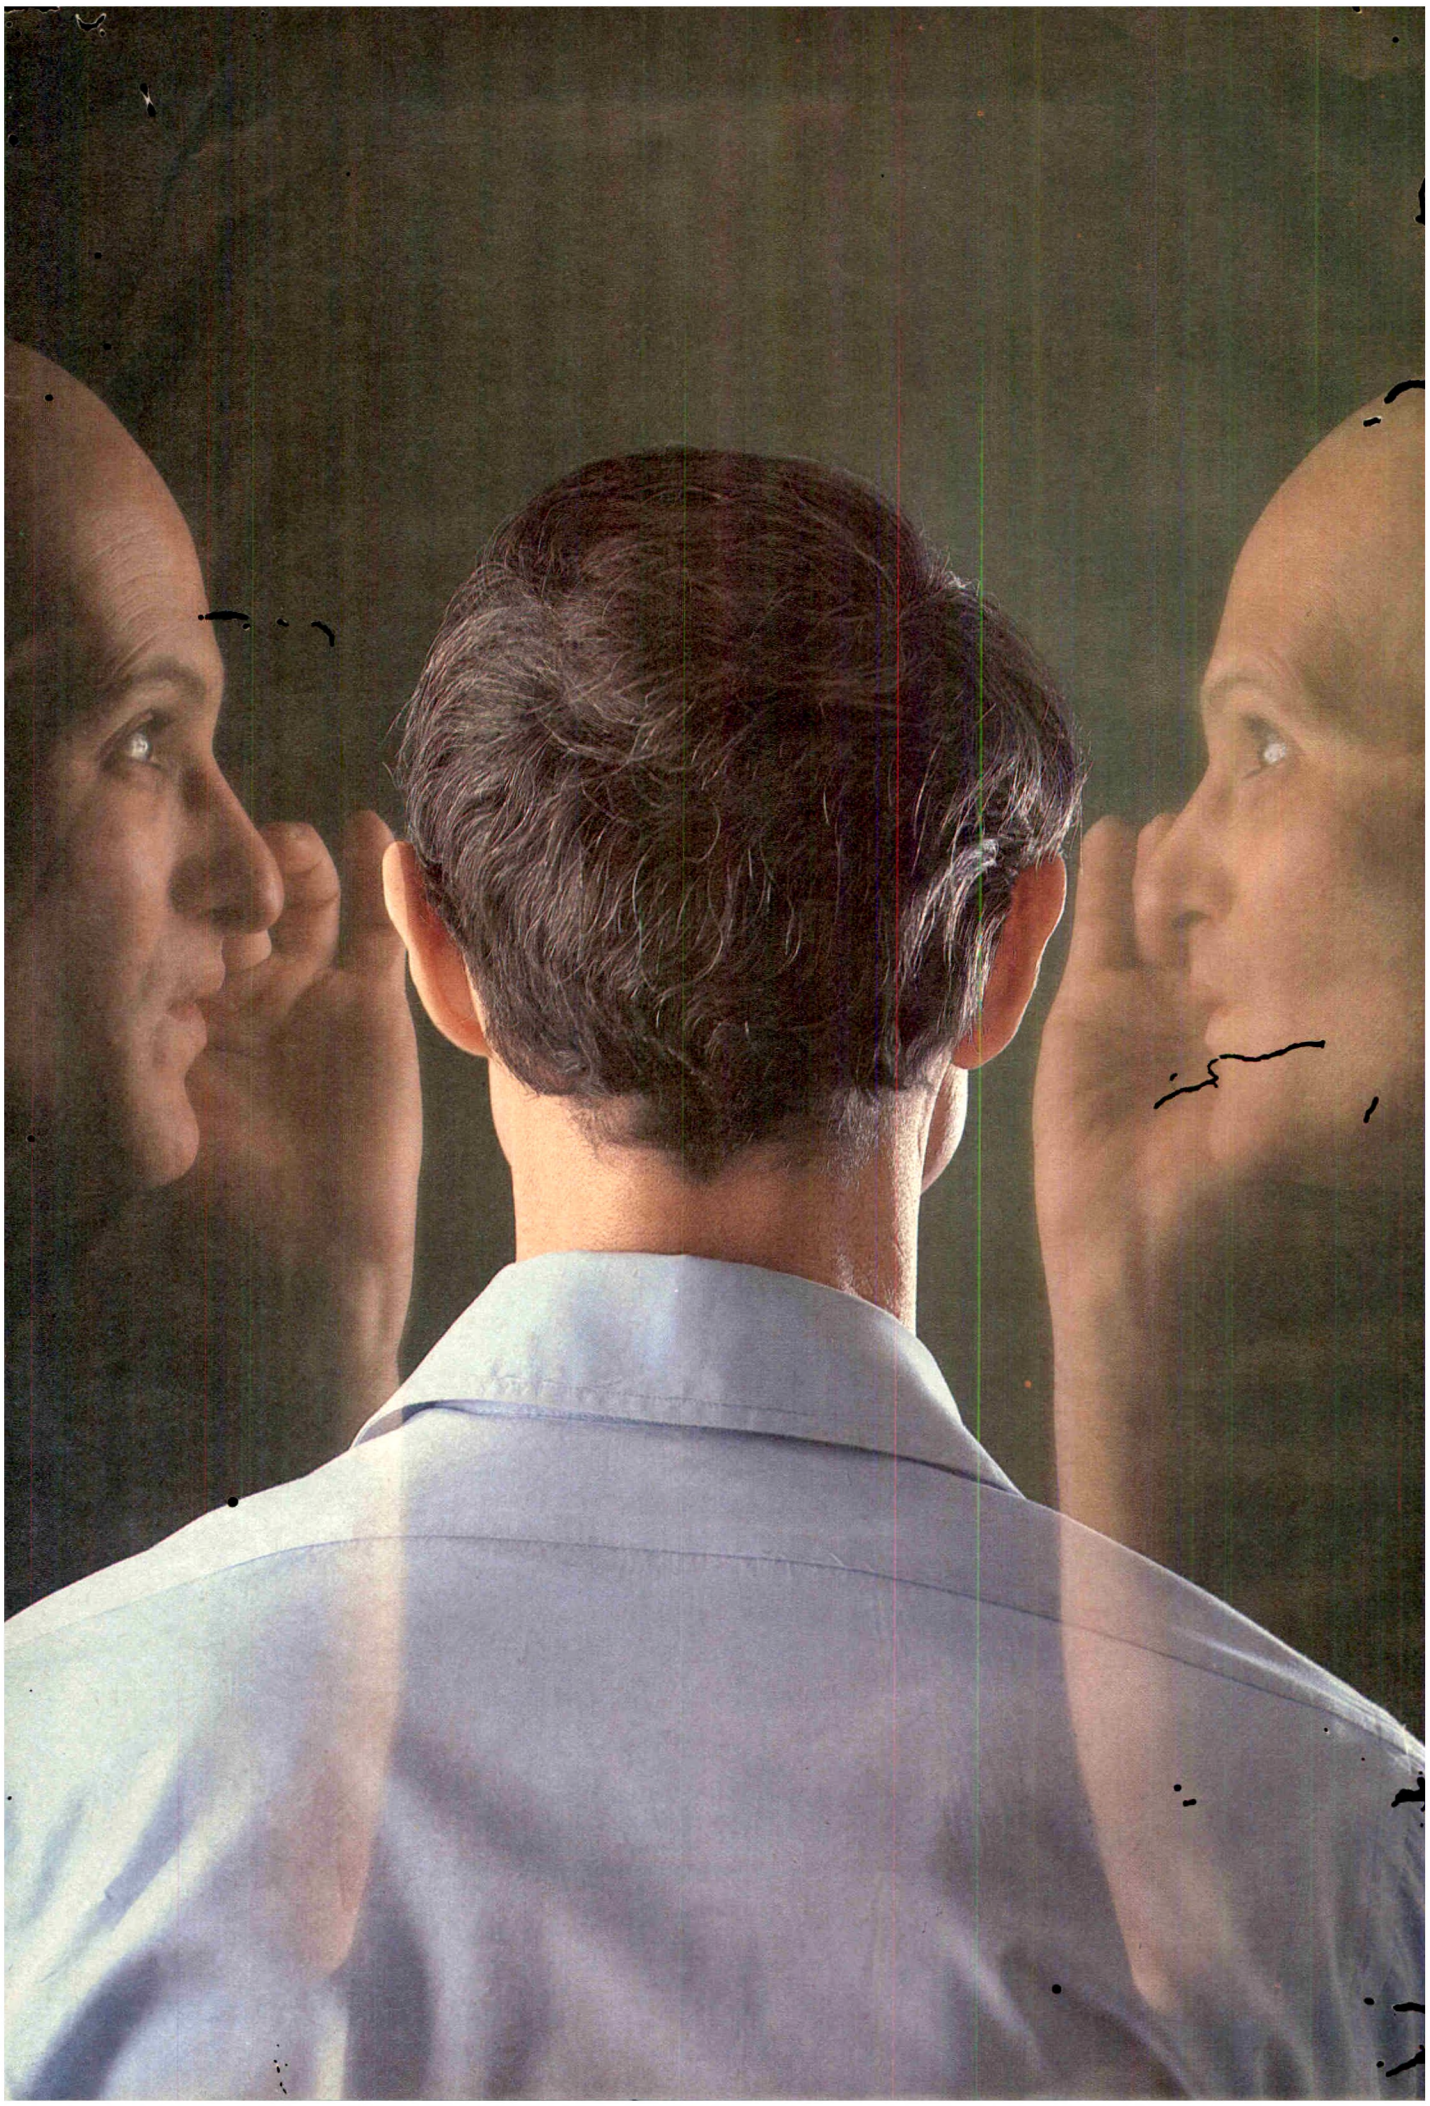
Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit use for educational purposes or of an author who wishes to reprint his/her own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS



No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Reprint orders from others should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

VOICES

...accusatory, derogatory, condemning, commanding.

Navane (thiothixene) rapidly controls auditory hallucinations as well as the agitation and hostility patterns they frequently generate.

Rapid control of psychotic symptoms on admission

Navane provides effective, rapid control of the major symptoms of psychosis including hallucinations, delusions, agitation, hostility, and thought disorders.[1-5] Navane promotes rapid progress, usually without the over-sedation or cardiovascular problems that can impede the therapeutic course.

Continued long-term improvement

Because Navane provides long-term outpatient control of psychotic symptoms, it can enable many patients to function effectively at home and on the job and to adjust rapidly to the community.[6]

Effectiveness rarely compromised by adverse reactions

Navane allows patients to remain alert and active, seldom causing over-sedation or drowsiness.[7] Hypotension and other cardiovascular reactions[5,6,8] are seldom reported and the occurrence of unpleasant anticholinergic side effects such as dry mouth or constipation is rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled through dosage adjustments or antiparkinson agents.

Rapid control
Long-term improvement

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml. Intramuscular 2 mg./ml.

*For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

ROERIG Pfizer

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

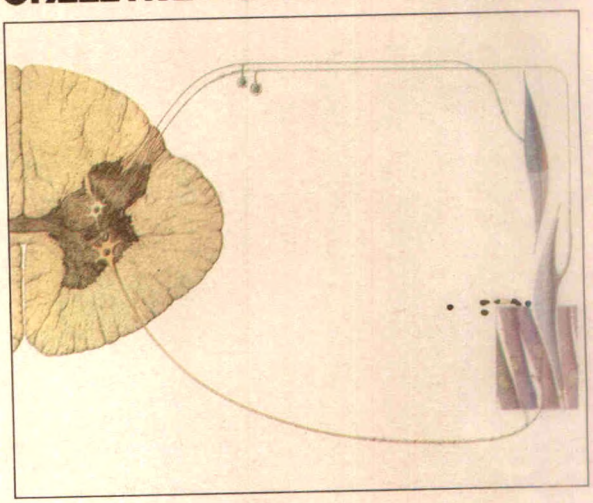
MIND & MUSCLE...



ONLY VALIUM (diazepam) HAS THESE TWO DISTINCT EFFECTS...

MIND: PSYCHOTHERAPEUTIC

Valium is useful for the relief of undue psychic tension and anxiety whether seen alone or associated with organic or functional disorders, or with secondary depressive symptoms. Valium provides a quality of response you know, want and trust. A response which has a pronounced effect on the somatic symptoms of anxiety.

MUSCLE: SKELETAL MUSCLE RELAXANT

Preliminary studies in both animals and humans have suggested that Valium (diazepam) may also work at the spinal level by enhancing presynaptic inhibition, a mechanism believed to diminish spasm in skeletal muscle. Clinically, adjunctive Valium has significant skeletal muscle relaxant properties.

VALIUM® (diazepam) IV

2-MG, 5-MG, 10-MG SCORED TABLETS

FOR THE RESPONSE YOU KNOW, WANT AND TRUST

Before prescribing, please see following page for a summary of product information.

ROCHE

VALIUM®
(diazepam)

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

The effectiveness of Valium in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should periodically reassess the usefulness of the drug for the individual patient.

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

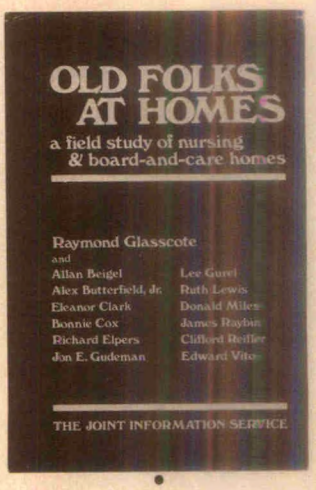
The Joint Information Service of the American Psychiatric Association and the Mental Health Association releases Two New Volumes That

Focus on the Elderly



This carefully documented book reports a field study of ten programs, four in America and six in England and Scandinavia, which serve as practical demonstrations of creative mental health services for the elderly. They include:

- a novel "Neighborhood Family" providing vigorous support to elderly residents of several trailer parks
- a high school for the elderly which sends its students abroad for study trips
- a "Human Development Project" that focuses on responding to the psychological needs of the elderly
- a carefully coordinated system of "respite hospitalization," which promotes the health of the elderly while allowing maximum use of hospital beds and family resources
- a "Lucy Booth," patterned after the Peanuts comic strip, which provides easy access to many kinds of services
- and many other innovative, successful approaches.

Each program is subjected to intensive scrutiny. The resulting document becomes a handbook, and, as well, a forum through which some of the world's most experienced practitioners of "the psychiatry of old age" present their views.

Dr. Wilma Donohue, director of the International Center for Social Gerontology, characterizes this volume as "a masterful job of putting everything in relief . . . the guidelines for action are right here."

190 pages. Casebound. Price $8.50.

Concerned about the very bad reputation that nursing homes have received from many quarters in recent years, the Joint Information Service set up a field study to visit a systematically chosen sample of nursing homes, and board-and-care homes as well, to see to what extent the care of and the quality of life for the patients differed from the geriatrics units of state hospitals. Altogether, sixty nursing homes and 31 board-and-care homes in ten locales were visited, in each case by the senior author accompanied by two mental health professionals.

The teams were surpised to learn that care and quality of life in many of the nursing and board-and-care homes they visited were better—sometimes dramatically better—than that in the mental health facilities and often at lower cost.

This unique publication provides an overview of all facilities visited plus vignettes of approximately half. Federal and state rules and regulations are also expertly synthesized into brief and readable style.

148 pages. Casebound. Price $6.50

ANTIDEPRESSANT EFFECTIVENESS with convenient once-a-day *h.s.* dosage*

NEW 150-MG CAPSULE†

Also available in:
100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

†The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)
NEW 150-MG CAPSULE*

*The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting daily dose of 75 mg is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-day dosage schedule. If the once-a-day schedule is employed the maximum recommended dose is 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.**

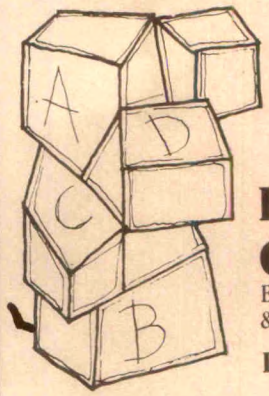
Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus), hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.



B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days, since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg and 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 mg doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not with grape juice. Preparation and storage of bulk dilutions is not recommended.

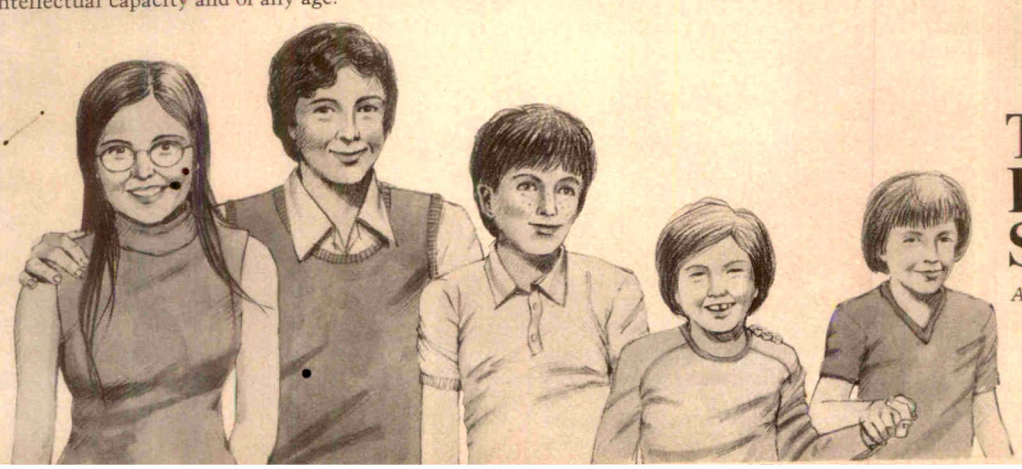
BUTTERWORTH GROUP

AJP7-8

Flexibility is our forte: The Brown Schools

Because we maintain great flexibility at all three of our treatment centers, each resident follows an individualized plan of treatment, training, education and care prescribed for that resident alone.

And we believe that residential treatment conducted in this highly individualized manner still is the most effective treatment for many. Our large, experienced staff is skilled in the treatment of children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.



Our three treatment centers are geographically separated to provide the appropriate residential milieu, yet close enough that residents benefit from the comprehensive training and expertise of the entire staff. All three are psychiatrically oriented, so that we are prepared to treat emotional disturbance in persons of any intellectual capacity and of any age.

Patients become easier to manage

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent.
- not a phenothiazine

P 24, 350

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information.

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

For complete prescribing information, please see next page.

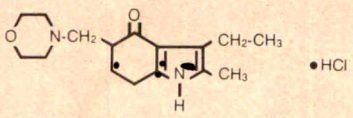
DUPONT

Patients become easier to manage on



MOBAN®

molindone HCl

5 mg	10 mg	25 mg
Endo	Endo	Endo

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose—
20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose—
20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose—
5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN® Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencies and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

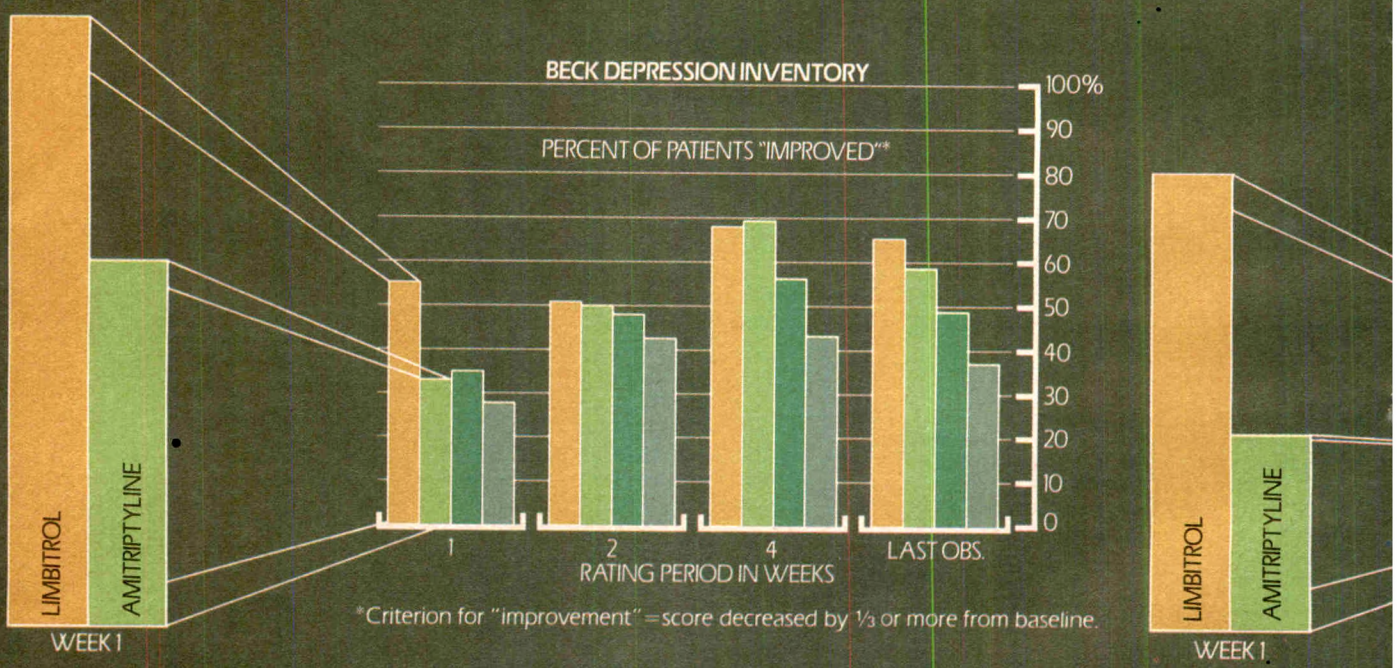
Within one week
A better response
For twice as many patients

compared to amitriptyline alone

New Limbitrol® IV

For rapid relief of symptoms in moderate to severe depression and anxiety

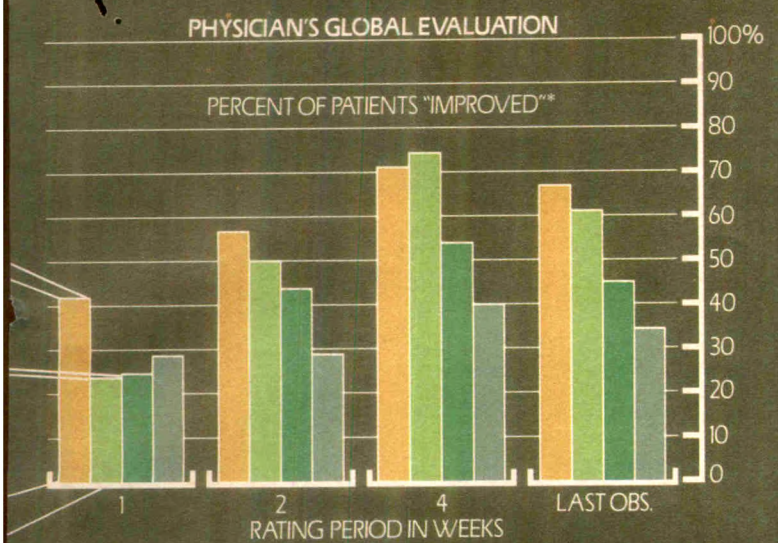


ROCHE

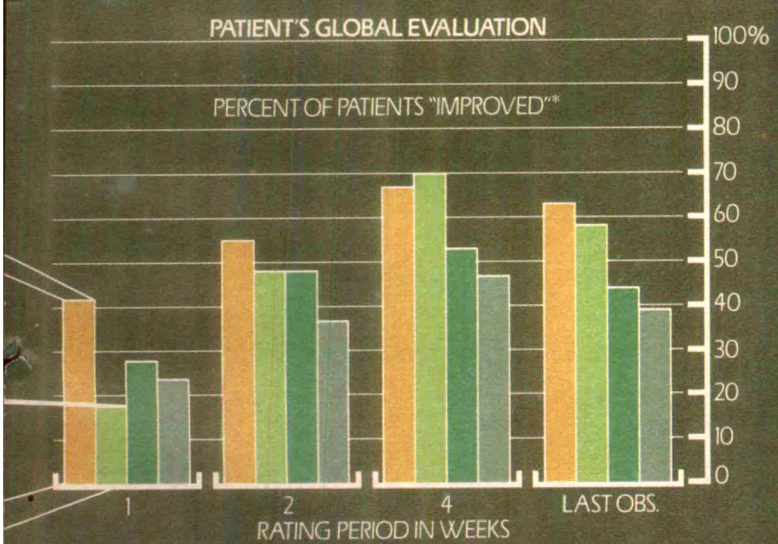
Please see last page of this advertisement for complete product information.

Within one week Twice as many patients improved–

*Criterion for "improvement" = score decreased by ½ or more from baseline.



*Criterion for "improvement" = score decreased by ⅓ or more from baseline.



New Limbitrol

Provides the well established antidepressant effect of amitriptyline with the proven antianxiety effect of Librium® (chlordiazepoxide HCl)

sooner than with amitriptyline alone

*Criterion for "improvement" = ratings of "much better" or "very much better."

*Criterion for "improvement" = ratings of "much better" or "very much better."

In a rigidly controlled nationwide multicenter study

The rating scales agree

- ☐ Patients respond faster
  - ☐ Limbitrol—approximately 2/3 of those who will improve will have done so by week one
  - ☐ Amitriptyline—only about 1/3 of those who will eventually respond will have done so by week one
- ☐ Greater overall improvement
- ☐ High correlation between major indices

LIMBITROL

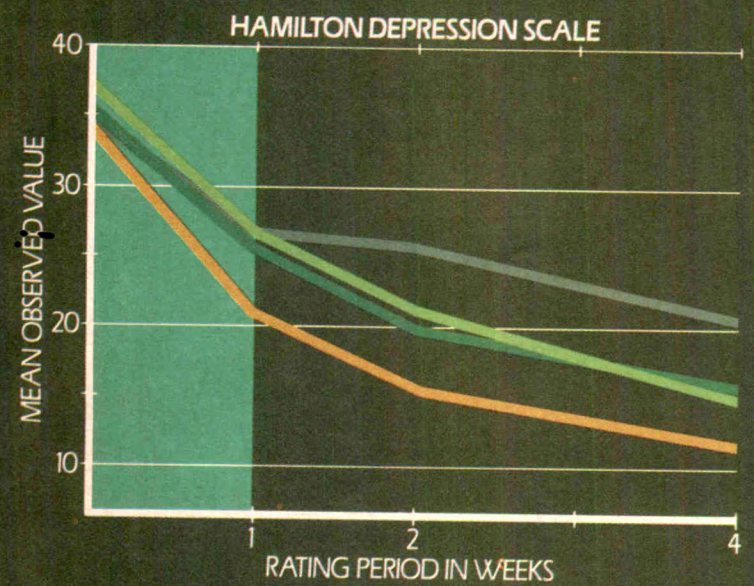
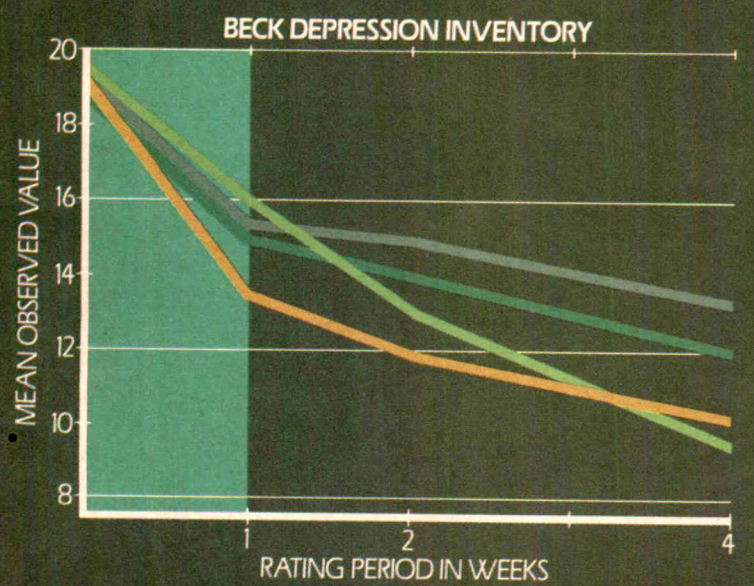
CHLORDIAZEPOXIDE
PLACEBO



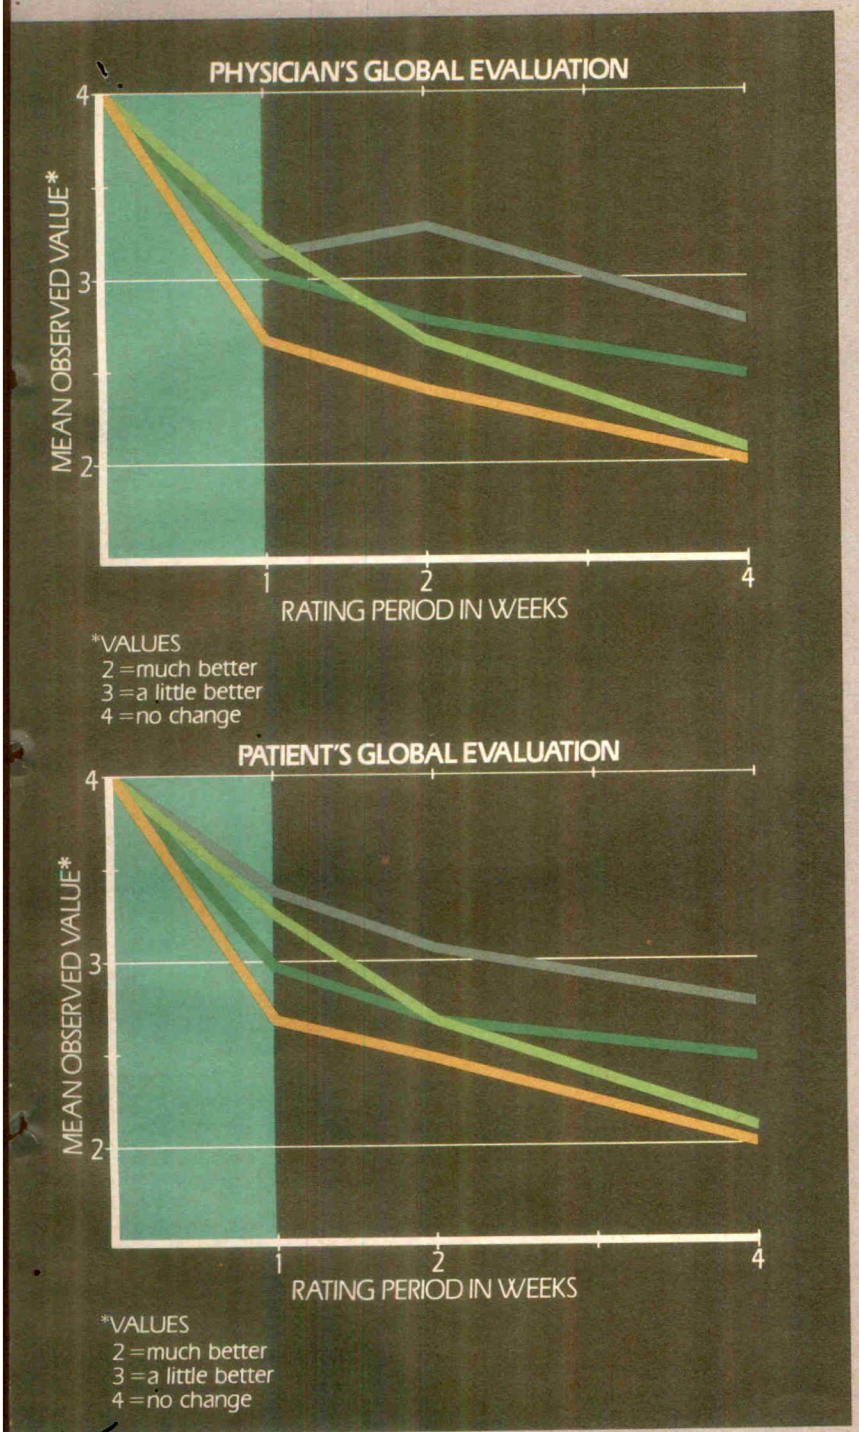
The data presented in this booklet are based on a rigidly controlled nationwide multicenter study of 279 patients with a diagnosis of primary depression and anxiety of moderate to severe degree



For rapid relief of moderate to severe depression and anxiety

ROCHE

Please see last page of this advertisement for complete product information.



Within one week
Marked reduction in severity of symptoms

New Limbitrol®

–better than amitriptyline alone

In a rigidly controlled nationwide multicenter study

The symptoms subside

Hamilton Depression Scale Items

- ☐ insomnia
- ☐ psychic anxiety
- ☐ somatic anxiety
- ☐ agitation
- ☐ suicidal ideation
- ☐ worthlessness

Beck Depression Inventory Items

- ☐ pessimism
- ☐ dissatisfaction
- ☐ guilt
- ☐ social withdrawal
- ☐ anorexia

Physician's and Patient's Global Evaluations

As measured by the Physician's and Patient's Global Evaluations, Limbitrol was rated superior to amitriptyline.

LIMBITROL
AMITRIPTYLINE
CHLORDIAZEPOXIDE
PLACEBO

For rapid relief of moderate to severe depression and anxiety

ROCHE

Please see last page of this advertisement for complete product information.

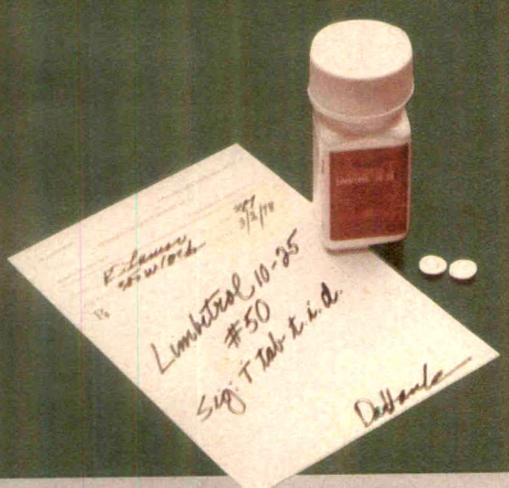
Within one week
Twice as many patients responded as

New Limbitrol®

Tablets 10-25 each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt)

Tablets 5-12.5 each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)

with amitriptyline alone



In a rigidly controlled nationwide multicenter study

The therapy succeeds

- ☐ Better patient compliance
- ☐ Lower dropout rate
  - ☐ The dropout rate due to side effects was lower with Limbitrol than with amitriptyline alone (Limbitrol 4%, amitriptyline 13%, chlordiazepoxide 1%)
  - ☐ The dropout rate due to therapeutic failure was lower with Limbitrol (Limbitrol 2%, amitriptyline 6%, chlordiazepoxide 12%)

(While the frequency of side effects was comparable between Limbitrol and amitriptyline, drowsiness occurred more often with Limbitrol.)

- ☐ Free of major phenothiazine drawbacks

How to initiate and maintain therapy

For most patients

☐ Limbitrol 10-25 is recommended in an initial dosage of three or four tablets daily in divided doses.

For elderly patients and patients who do not tolerate higher doses

☐ Limbitrol 5-12.5 is recommended in an initial dosage of three or four tablets daily in divided doses.

For all patients

- ☐ Dosage should be individualized on the basis of symptom severity and response.
  - ☐ Because drowsiness is a common side effect, it may be preferable to give the larger portion of the total daily dose at bedtime. Not only will this help minimize problems with daytime drowsiness, it may also help relieve a major target symptom—insomnia.
  - ☐ Some patients respond to smaller doses or to a single dose at bedtime.
  - ☐ Dosage may be increased up to six tablets or decreased to two tablets daily as necessary.
- ☐ Once a satisfactory response is obtained, reduce dosage to the smallest amount needed to maintain remission.
- ☐ Warning: Since Limbitrol contains chlordiazepoxide, a minor tranquilizer, usage during the first trimester of pregnancy should almost always be avoided.

For rapid relief of moderate to severe depression and anxiety

ROCHE

Please see last page of this advertisement for complete product information.

Limbitrol®
Tablets

Tranquilizer—Antidepressant

Limbitrol 10-25

Each tablet contains 10 mg chlordiazepoxide and 25 mg amitriptyline in the form of the hydrochloride salt.

Limbitrol 5-12.5

Each tablet contains 5 mg chlordiazepoxide and 12.5 mg amitriptyline in the form of the hydrochloride salt.

Description: Limbitrol combines in a tablet for oral administration, chlordiazepoxide, an agent for the relief of anxiety and tension, and amitriptyline, an antidepressant.

Chlordiazepoxide is a benzodiazepine with the formula 7-chloro-2-(methylamino)-5-phenyl-3*H*-1,4-benzodiazepine 4-oxide. It is a slightly yellow crystalline material and is insoluble in water. The molecular weight is 299.76.

Amitriptyline is a dibenzocycloheptadiene derivative. The formula is 10,11-dihydro-*N*,*N*-dimethyl-5H-dibenzo [a, d] cycloheptene-Δ^{5Y}-propylamine hydrochloride. It is a white or practically white crystalline compound that is freely soluble in water. The molecular weight is 313.87.

Actions: Both components of Limbitrol exert their action in the central nervous system. Extensive studies with chlordiazepoxide in many animal species suggest action in the limbic system. Recent evidence indicates that the limbic system is involved in emotional response. Taming action was observed in some species. The mechanism of action of amitriptyline in man is not known, but the drug appears to interfere with the reuptake of norepinephrine into adrenergic nerve endings. This action may prolong the sympathetic activity of biogenic amines.

Indications: Limbitrol is indicated for the treatment of patients with moderate to severe depression associated with moderate to severe anxiety.

The therapeutic response to Limbitrol occurs earlier and with fewer treatment failures than when either amitriptyline or chlordiazepoxide is used alone.

Symptoms likely to respond in the first week of treatment include: insomnia, feelings of guilt or worthlessness, agitation, psychic and somatic anxiety, suicidal ideation and anorexia.

Contraindications: Limbitrol is contraindicated in patients with hypersensitivity to either benzodiazepines or tricyclic antidepressants. It should not be given concomitantly with a monoamine oxidase inhibitor. Hyperpyretic crises, severe convulsions and deaths have occurred in patients receiving a tricyclic antidepressant and a monoamine oxidase inhibitor simultaneously. When it is desired to replace a monoamine oxidase inhibitor with Limbitrol, a minimum of 14 days should be allowed to elapse after the former is discontinued. Limbitrol should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. This drug is contraindicated during the acute recovery phase following myocardial infarction.

Warnings: Because of the atropine-like action of the amitriptyline component, great care should be used in treating patients with a history of urinary retention or angle-closure glaucoma. In patients with glaucoma, even average doses may precipitate an attack. Severe constipation may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressant drugs, particularly when given in high doses, have been reported to produce arrhythmias, sinus tachycardia and prolongation of conduction time. Myocardial infarction and stroke have been reported in patients receiving drugs of this class.

Usage in Pregnancy: Safe use of Limbitrol during pregnancy and lactation has not been established. Because of the chlordiazepoxide component, please note the following:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physicians about the desirability of discontinuing the drug.

Physical and Psychological Dependence: Physical and psychological dependence to Limbitrol have not been reported. However, since physical and psychological dependence to chlordiazepoxide have been reported rarely, caution must be exercised in administering Limbitrol to individuals known to be addiction-prone or to those whose history suggests they may increase the dosage on their own initiative.

Withdrawal symptoms from Limbitrol have not been reported. However, withdrawal symptoms following abrupt cessation of prolonged therapy with either component alone have been reported. With amitriptyline, these have been noted to consist of nausea, headache and malaise; for chlordiazepoxide, the symptoms (including convulsions) are similar to those seen with barbiturates.

Precautions: *General:* Use with caution in patients with a history of seizures.

Close supervision is required when Limbitrol is given to hyperthyroid patients or those on thyroid medication.

The usual precautions should be observed when treating patients with impaired renal or hepatic function.

Patients with suicidal ideation should not have easy access to large quantities of the drug. The possibility of suicide in depressed patients remains until significant remission occurs.

Information for the Patient: Because of the sedative effects of Limbitrol, patients should be cautioned about combined effects with alcohol or other CNS depressants. The additive effects may produce a harmful level of sedation and CNS depression.

Patients receiving Limbitrol should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as operating machinery or driving a motor vehicle.

Essential Laboratory Tests: Patients on prolonged treatment should have periodic liver function tests and blood counts.

Drug and Treatment Interactions: Because of its amitriptyline component, Limbitrol may block the antihypertensive action of guanethidine or compounds with a similar mechanism of action.

The effects of concomitant administration of Limbitrol and other psychotropic drugs have not been evaluated. Sedative effects may be additive.

The drug should be discontinued several days before elective surgery.

Concurrent administration of ECT and Limbitrol should be limited to those patients for whom it is essential.

Pregnancy: See WARNINGS section.

Nursing Mothers: It is not known whether this drug is excreted in human milk. As a general rule, nursing should not be undertaken while a patient is on a drug, since many drugs are excreted in human milk.

Pediatric Use: Safety and effectiveness in children below the age of 12 years have not been established.

Elderly Patients: In elderly and debilitated patients it is recommended that dosage be limited to the smallest effective amount to preclude the development of ataxia, oversedation, confusion or anticholinergic effects.

Adverse Reactions: Adverse reactions to Limbitrol are those associated with the use of either component alone. Most frequently reported were drowsiness, dry mouth, constipation, blurred vision, dizziness and bloating. Other side effects occurring less commonly included vivid dreams, impotence, tremor, confusion and nasal congestion. Many symptoms common to the depressive state, such as anorexia, fatigue, weakness, restlessness and lethargy, have been reported as side effects of treatment with both Limbitrol and amitriptyline.

Granulocytopenia, jaundice and hepatic dysfunction of uncertain etiology have also been observed rarely with Limbitrol. When treatment with Limbitrol is prolonged, periodic blood counts and liver function tests are advisable.

Note: Included in the listing which follows are adverse reactions which have not been reported with Limbitrol. However, they are included because they have been reported during therapy with one or both of the components or closely related drugs.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Euphoria, apprehension, poor concentration, delusions, hallucinations, hypomania and increased or decreased libido.

Neurologic: Incoordination, ataxia, numbness, tingling and paresthesias of the extremities, extrapyramidal symptoms, syncope, changes in EEG patterns.

Anticholinergic: Disturbance of accommodation, paralytic ileus, urinary retention, dilatation of urinary tract.

Allergic: Skin rash, urticaria, photosensitization, edema of face and tongue, pruritus.

Hematologic: Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue.

Endocrine: Testicular swelling and gynecomastia in the male, breast enlargement, galactorrhea and minor menstrual irregularities in the female and elevation and lowering of blood sugar levels.

Other: Headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, jaundice, alopecia, parotid swelling.

Overdosage: There has been limited experience with Limbitrol overdosage *per se;* the manifestations of overdosage and recommendations for treatment are based on clinical experience with its components. Primary concern should be with the dangers associated with amitriptyline overdosage. Deaths by deliberate or accidental overdosage have occurred with this class of drugs.

All patients suspected of having an overdosage of Limbitrol should be admitted to a hospital as soon as possible.

Manifestations: High doses may cause drowsiness, temporary confusion, disturbed concentration or transient visual hallucinations. Overdosage may cause hypothermia, tachycardia and other arrhythmias, ECG evidence of impaired conduction (such as bundle branch block), congestive heart failure, dilated pupils, convulsions, severe hypotension, stupor and coma. Other symptoms may be agitation, hyperactive reflexes, muscle rigidity, vomiting, hyperpyrexia or any of those listed under Adverse Reactions.

Treatment: Empty the stomach as quickly as possible by emesis or lavage. In the comatose patient a cuff endotracheal tube should be placed in position prior to either of these measures. The instillation of activated charcoal into the stomach also should be considered. If the patient is stuporous but responds to stimuli, only close observation and nursing care may be required. It is essential to maintain an adequate airway and fluid intake. Body temperature should be watched closely and appropriate measures taken should deviations occur.

The intramuscular or slow intravenous administration of 1 to 3 mg in adults (or 0.5 mg in children) of physostigmine salicylate (Antilirium)[1-3] has been reported to reverse the manifestations of amitriptyline overdosage. Because of its relatively short half-life, additional doses may be needed at intervals of 30 minutes to 2 hours.

Convulsions may be treated by the use of an inhalation anesthetic rather than the use of barbiturates. Cardiac monitoring is advisable, and the cautious use of digitalis or other antiarrhythmic agents should be considered if serious cardiovascular abnormalities occur. Serum potassium levels should be monitored and kept within normal limits by the use of appropriate I.V. fluids. Standard measures including oxygen, I.V. fluids, plasma expanders and corticosteroids may be used to control circulatory shock.

Dialysis is unlikely to be of value, as it has not proven useful in overdosages of either amitriptyline or chlordiazepoxide. Since many suicidal attempts involve multiple drugs including barbiturates, the possibility of dialysis being beneficial for removal of other drugs should not be overlooked.

Treatment should be continued for at least 48 hours, along with cardiac monitoring in patients who do not respond to therapy promptly. Since relapses are frequent, patients should be hospitalized until their conditions remain stable without physostigmine for at least 24 hours.

Since overdosage is often deliberate, patients may attempt suicide by other means during the recovery phase.

Dosage and Administration: Optimum dosage varies with the severity of the symptoms and the response of the individual patient. When a satisfactory response is obtained, dosage should be reduced to the smallest amount needed to maintain the remission. The larger portion of the total daily dose may be taken at bedtime. In some patients, a single dose at bedtime may be sufficient. In general, lower dosages are recommended for elderly patients.

Limbitrol 10-25 is recommended in an initial dosage of three or four tablets daily in divided doses; this may be increased to six tablets daily as required. Some patients respond to smaller doses and can be maintained on two tablets daily.

Limbitrol 5-12.5 in an initial dosage of three or four tablets daily in divided doses may be satisfactory in patients who do not tolerate higher doses.

How Supplied: White, film-coated tablets, each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt) and blue, film-coated tablets, each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 50.

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

FLEXIBLE DOSAGE TO MEET THE INTENSITY OF ANXIETY

☐ for clinically manifest neurotic or psychoneurotic anxiety, and anxiety associated with somatic disease†

Approximate Milligram Equivalency*

AZENE ™ Clorazepate monopotassium	Diazepam	Chlordi-azepoxide	Oxazepam
3.25 mg	2 mg	5 mg	10 mg
6.5 mg	5 mg	10 mg	15 mg
13.0 mg	10 mg	25 mg	30 mg

*Based upon available information from manufacturers' package inserts.

☐ an acceptable sedative profile

Drowsiness may occur at initiation of treatment, and with dosage increments.

Brief Summary of Prescribing Information

CONTRAINDICATIONS AZENE™ (clorazepate monopotassium) is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

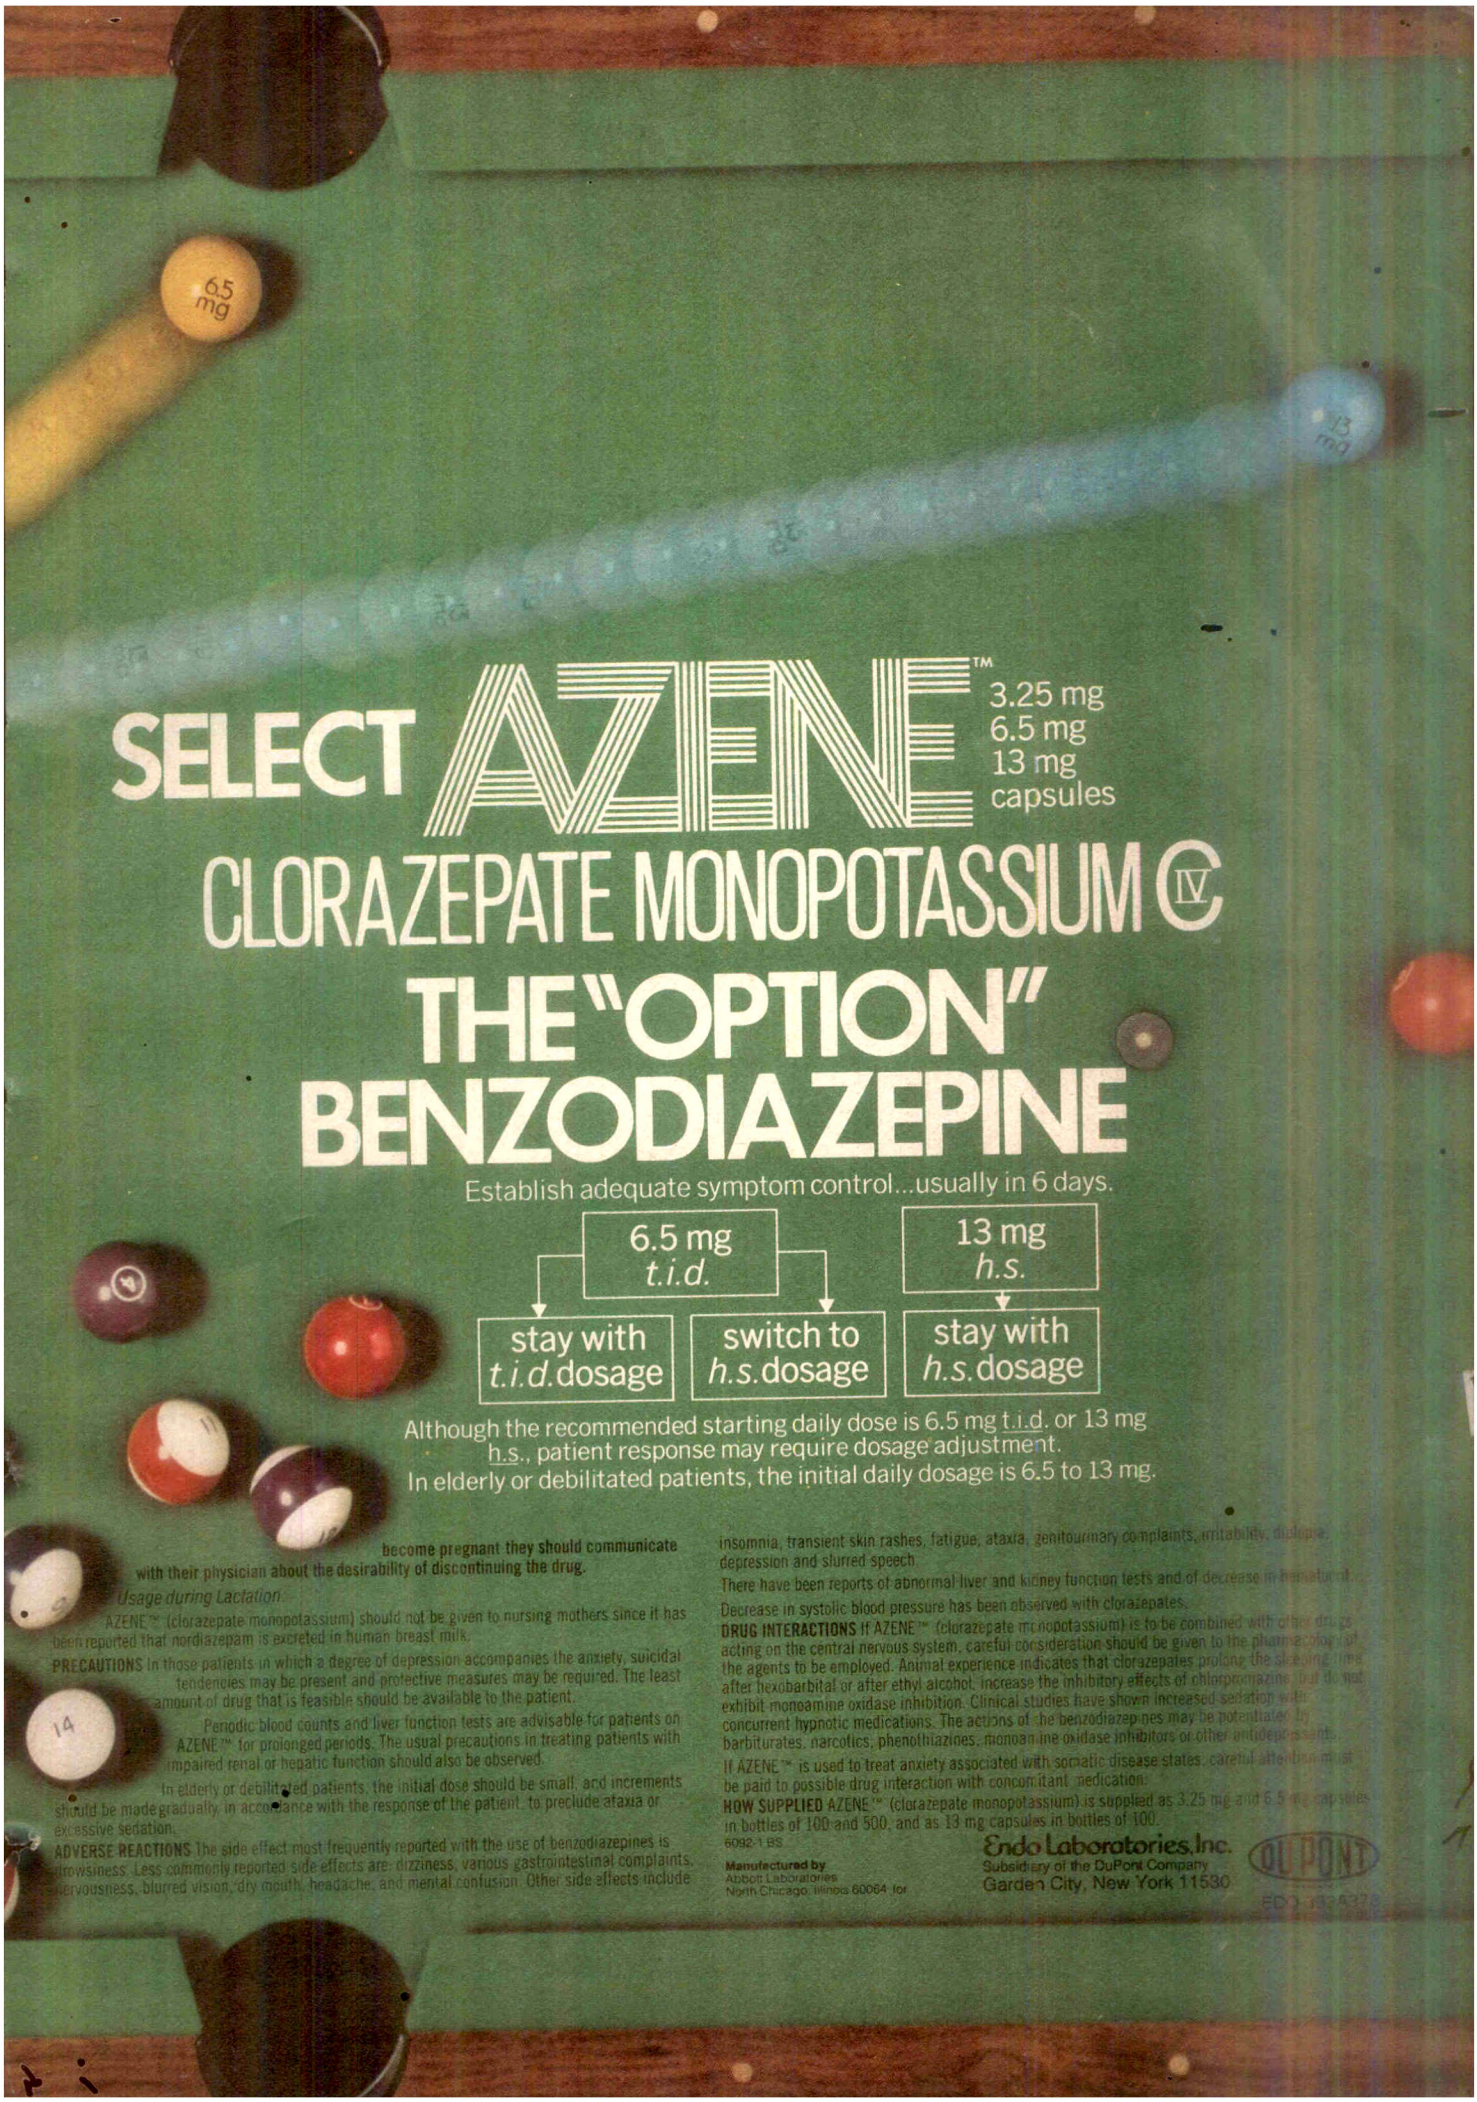
WARNINGS AZENE™ is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on AZENE™ should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since AZENE™ (clorazepate monopotassium) has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, AZENE™ is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepates. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.



Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Tolerance developed within 3 to 9 days in dogs. Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced, the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. AZENE,™ (clorazepate monopotassium) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to

†The effectiveness of AZENE™ in long-term use, that is, more than four months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

SELECT AZENE™
3.25 mg
6.5 mg
13 mg
capsules
CLORAZEPATE MONOPOTASSIUM C-IV
THE "OPTION" BENZODIAZEPINE
Establish adequate symptom control...usually in 6 days.
6.5 mg t.i.d.
13 mg h.s.
stay with t.i.d. dosage
switch to h.s. dosage
stay with h.s. dosage
Although the recommended starting daily dose is 6.5 mg t.i.d. or 13 mg h.s., patient response may require dosage adjustment.
In elderly or debilitated patients, the initial daily dosage is 6.5 to 13 mg.
become pregnant they should communicate with their physician about the desirability of discontinuing the drug.
Usage during Lactation
AZENE™ (clorazepate monopotassium) should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.
PRECAUTIONS In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.
Periodic blood counts and liver function tests are advisable for patients on AZENE™ for prolonged periods. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.
In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually in accordance with the response of the patient, to preclude ataxia or excessive sedation.
ADVERSE REACTIONS The side effect most frequently reported with the use of benzodiazepines is drowsiness. Less commonly reported side effects are: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.
There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.
Decrease in systolic blood pressure has been observed with clorazepates.
DRUG INTERACTIONS If AZENE™ (clorazepate monopotassium) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that clorazepates prolong the sleeping time after hexobarbital or after ethyl alcohol, increase the inhibitory effects of chlorpromazine, but do not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.
If AZENE™ is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.
HOW SUPPLIED AZENE™ (clorazepate monopotassium) is supplied as 3.25 mg and 6.5 mg capsules in bottles of 100 and 500, and as 13 mg capsules in bottles of 100.

The patient with clinically significant depression

He's getting better...

...and ELAVIL® is helping

(AMITRIPTYLINE HCl | MSD)

Helping with symptom relief

ELAVIL usually relieves a broad range of symptoms associated with depression, including sleep disturbance, one of the most frequently observed in the "constellation of symptoms," and usually the first symptom to respond to therapy.

And, the anxiety-reducing sedative component extends the drug's clinical value when depression is accompanied by symptoms of anxiety.

Helping with convenient dosage regimens

ELAVIL offers a variety of convenient dosage regimens. A once-daily bedtime regimen may be an effective prescribing option, particularly when taken by a depressed patient experiencing sleep disturbance. ELAVIL can also be prescribed in divided daily doses.

Providing a wide range of tablet strengths

ELAVIL offers six color-coded tablets, available in the following strengths: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg. And for special circumstances, an injectable form is available. Injection ELAVIL is supplied in 10-ml vials, 10 mg/ml.

ELAVIL (Amitriptyline HCl, MSD) should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For a brief summary of prescribing information, please see following page.

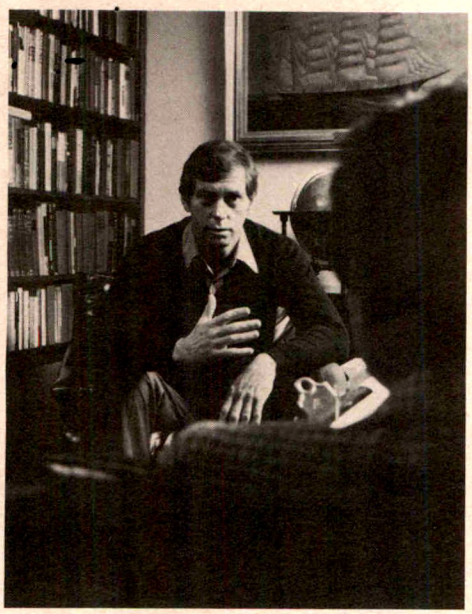
MSD
MERCK SHARP & DOHME

In clinically significant depression

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg
INJECTION: 10 mg per ml

Elavil®

(AMITRIPTYLINE HCl | MSD)



Single-entity antidepressant with an anxiety-reducing sedative component to its action

in clinically
significant depression

Elavil®

(AMITRIPTYLINE HCl | MSD)

Single-entity antidepressant with an anxiety-reducing sedative component to its action

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with amitriptyline HCl. Initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or a history of urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, increased intraocular pressure, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; tablets containing 150 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 30 and 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

Announcing Publication . . .

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

ANTIPSYCHOTIC EFFICACY... INFREQUENT EXTRAPYRAMIDAL SYMPTOMS

Antipsychotic medication should not interfere with the patient's ability to participate in your total therapeutic program. That is why Mellaril (thioridazine) is an excellent choice. It is highly effective, and although extrapyramidal symptoms are characteristic of this class of drug, with Mellaril (thioridazine) extrapyramidal stimulation—notably pseudoparkinsonism—is infrequent. Adding an anti-parkinsonian agent—which can cause its own side effects—can usually be avoided.

Mellaril (thioridazine) is not habituating and usually does not cause euphoria or undue sedation. (But, warn patients about undertaking activities requiring complete mental alertness.) And Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

©1977 Sandoz, Inc.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

FRANCIS J. BRACELAND, M.D.

THE AMERICAN JOURNAL OF PSYCHIATRY

Thirteen Years Before the Masthead—The Editor Retires

WHEN FRANCIS BRACELAND was piped aboard as Editor of the *American Journal of Psychiatry* in July of 1965, the signs were inauspicious. He set sail on his maiden voyage with a crew who, although imaginative and enthusiastic, were entirely new. He carried as cargo a massive backlog of unpublished manuscripts that sank his hull dangerously below the Plimsoll mark. And he was heading into the stormy seas of the late 1960s that were to threaten with shipwreck the leadership of more than one venerable institution. The odds at Lloyd's for a safe return to home port were bleak indeed. They were reckoned, however, without a proper reading of the new skipper and his crew.

The details of the first hectic months of Dr. Braceland's editorship will probably never be fully known, for they are buried in the intangibles of a multitude of critical and sensitive decisions, of the skill and hard work of dedicated editorial staff members, and of the strong loyalties that rapidly developed among the Editor, his associates, and his permanent staff. The results were readily visible in the initial productions of the new regime, and even a cursory glance at the early issues of Volume 122 gives clear evidence of a fresh wind blowing through the editorial office. Rapid review and accelerated publication procedures enabled the *Journal* to carry papers that had been presented only a few months before at the May annual meeting. Articles dealing with a single topic from various points of view were brought together in "Special Sections," and informative reviews provided the reader with careful surveys of clinical and laboratory research in a variety of fields. New and exciting areas of psychiatry made their debut in the *Journal*'s pages—the therapeutic use of lithium in affective disorders, for example, was introduced to many American psychiatrists in the September 1965 issue. Even the Letters to the Editor section took on new life as authors were permitted to respond to their critics in a dialogue that often clarified and enlarged upon the original paper. In all of these innovations are to be found the beginnings of what have since become regular features that have helped to make the *Journal* the flagship of psychiatric publications.

What of the skipper who has piloted his vessel so unerringly true to her course during 13 busy but happy years? In the papers that immediately follow the reader is privileged to hear from two people who know Francis Braceland well—Dr. Howard Rome, his close friend and colleague, and Ms. Evelyn Myers, who, as Managing Editor of the *Journal* throughout Dr. Braceland's editorship, has played a major role in its success. We are grateful to them both for their descriptions of their rich and rewarding associations with him and for so vividly painting for us his erudition, his humor, his kindly warmth, and the integrity, sound judgment, and fairness of his editorial criticisms—characteristics that endear him to us all and make us grateful that, as Editor Emeritus, he will stay aboard as an active hand in the running of the *Journal*.

Tossed on the ceaseless flood of manuscripts that is an editor's lot, Dr. Braceland has never lost his way on the trackless sea of words that has been his home these past 13 years. Many decades ago Frederick Rolfe, that curious and troubled scourge of editors and publishers alike, proclaimed in the peculiarly pungent, frenetic, sometimes vitriolic tones that characterize his style, "I detest, and denounce as criminal that finite mortal man who (having found a groove which fits his atrophied brain and hypertrophied organs) screams to Kosmos, 'This is the way, the only way; and, if you won't mutilate yourself to fit it, then be damned to you, you're dotty, balmy on the crumpet, impossible, and you practise the Bulgarian Heresy!' And so on. 'But the minds of the prudent are flexible: for the language of mortals is voluble; and the discourses thereof are numerous and varied; and vast is the distribution of words here and there.' I hold, with the Primate-Poet, that there is room for all opinions, for all systems, each in its convenient sphere. . . ." (1).

There is a message here for our turbulent, often intolerant modern age—a message that is the star, perhaps above all others, by which Francis Braceland has steered his ship. *Deo volente*, the *Journal* will remain on course.

Francis J. Braceland, the Man

BY HOWARD P. ROME, M.D.

WHEN ONE IS COMMISSIONED to do a portrait of a man, it is expected that he will render his subject realistically. In the style that is de rigueur in these days of investigative reporting, it certainly means not disguising the warts; indeed, all blemishes have to be exposed, and crow's-feet and various other wrinkles have to be noted as the telltale marks of being over the hill. But what does one say when the subject you are asked to portray has for years boldly displayed his wrinkles as the heraldic chevrons they are and furthermore celebrates in numerous writings his "advancing dotage" with scintillating wit and brilliantly humorous one-liners? Although the man in question pretends to be "naught but a hewer of wood and a drawer of water," his industry would be prodigious for a man half his years. And what is more, he actually makes what he does appear to be mundane, hence effortless.

Francis James Braceland, the man, will be an octogenarian in two years. I have to modify his claim that he is "in the metallic age," for, although there may be silver in his hair and gold in his teeth, there is *no* lead in his Sitz-platz. His long list of current activities refutes this public confession about plumbism being responsible for his slowing down. His raillery about his own aging process has become his stock-in-trade as a much sought after speaker on retirement and other aspects of gerontology. This artful dissembling is typical of his tolerant acceptance of life's vicissitudes over a span of 78 years.

EARLY YEARS

Frank's early years could have been the model of those true-grit-shall-prevail, Horatio Alger classics that were famous for exhorting and inspiring disadvantaged young men in the nineteenth century and early decades of this century. His father, John, died when Frank was four years old, leaving his widow, Margaret, to rear their three children. Frank and his younger brothers Joe and Paul learned at an early age to scrimp and scrape for everything. In the economic doldrums before World War I the going was tough.

"Brewerytown," where the Braceland family lived in Philadelphia, was a rough and tumble place in which status and hence respect were earned in the school of hard knocks by fight or flight; the young Frank Braceland learned how to do both. This was quite the opposite of the conducive milieu that Jacques Barzun has said is necessary for a child "to be at home in the House of Intellect," to which the Bracelands aspired.

Frank was 26 years old when, at last, he graduated from La Salle College in Philadelphia; he had to work his way through high school and college. Fifteen years later his alma mater awarded him the first of his twelve honorary degrees. He also has the distinction of being a ten-year member of La Salle's Board of Trustees.

Doctor Braceland graduated from Jefferson Medical College in the Depression year of 1930. In recognition of his literary contributions, Jefferson honored him with the Doctor of Letters degree 35 years later; as a distinguished alumnus, he has been a member of its Board of Trustees. He won a coveted internship and was chief resident in its hospital and after two years, because of a touching experience as a physician caring for a patient in the throes of a depression, decided on psychiatry in preference to other intriguing opportunities that had come his way.

Kirkbride's Hospital, as the 44th Street branch of the Pennsylvania Hospital was known to Philadelphians, had actually been founded by Benjamin Rush. It was a private mental hospital. In the days when Thomas Kirkbride was its superintendent, the 44th Street hospital was out in the country, and in the 1930s, when Frank began his residency, it was still not crowded. The impressive stone walls gave a sense of sanctuary reinforced by spacious, well-kept grounds. In the middle of a plot in front of its Georgian portico there stood a large magnolia tree. The date of its flowering each spring has been duly noted in Spencerian script in the manager's minutes recorded in huge journals. It was a beautiful old place. Frank Braceland fell in love with it and was willing to settle in for the rest of his professional life.

THE SEARCH FOR PHYSICAL AGENTS

His years of intimate association with Doctors Eyman, Bond, Strecker, Appel, Smith, and Palmer coincided with the seeding of modern psychiatry. The bloom that attracted interest was the spectacular discovery of Wagner-Jauregg, whose treatment of paresis was the first to really try to cure a devastating mental illness. It won him the Nobel Prize. Braceland, as a resident physician, quickly learned the knack of keeping a strain of malarial parasites viable by the inoculation of successive luetic patients with whole

Dr. Rome is Professor of Psychiatry (Emeritus), Mayo Graduate School of Medicine, Rochester, Minn. 55901.

0002-953X/78/0007-0784$0.50 © 1978 American Psychiatric Association

blood drawn at the height of the malarial fever. Naturally, this dramatic treatment lent credence to the search for equally successful physical agents for the treatment of the functional psychoses.

In his omnivorous reading, Frank had read of Cotton's enthusiastic report of treatment by surgical removal of the sites of focal infection but strenuously objected to much of the procedure. He said that making semicolons out of colons would not cure schizophrenia. However, there were always one or two patients on the wards of 44th Street who were being treated with a variant of Klaesi's *Dauerschlaf* (narcosis therapy).

Braceland, an avid and enterprising student of "The New Psychiatry," was enlisted in an enthusiastic search for yet another successful physical treatment of baffling disorders. His first publication, in 1934, was titled "Hematoporphyrin as Therapeutic Agent in Psychoses" (1). Doctors Strecker and Palmer were its senior authors. This study was of a mixed group of long-term chronic psychotic patients who were given both intramuscular and oral doses of hematoporphyrin. The rationale for the treatment was its reported success by European investigators.

A more explicit rationale for the use of these exotic agents appeared as a prefatory paragraph in a 1935 paper titled "Aschner Treatment of Schizophrenia: Therapeutic Note" (2); this was published with Doctors Appel and Farr as the senior authors. Its justification begins,

> For the last 20 years, there has been a revival of interest in the constitutional aspect of disease, first in Germany, more recently in the United States. The leaders of this movement have aimed to integrate the scientific advances of the last 75 years in genetics, morphology, physiology and allied branches.

The conclusions were that "results are . . . disappointing. . . . In the majority of cases [any results were] *only* temporary."

As a bright and enthusiastic young resident, Frank eagerly sought opportunities to interlard his daily routine of psychotherapeutic sessions with an assigned group of patients and the usual administrative chores that are the lot of all tyro-psychiatrists. The congenial atmosphere of the Pennsylvania Hospital encouraged this. Then, too, the time was conducive. Psychiatry was on the move, galvanized by two vastly different currents—psychoanalysis and its variants and, at the opposite pole, what was coming to be biologically oriented research. Our man, F.J.B., was caught in the intellectual turbulence.

By happy coincidence he finished his formal training in time to be chosen as one of several special traveling Rockefeller Fellows. His turmoil in choosing between Zurich and Vienna was resolved by Dr. Earl Bond's advice. He applied for and was accepted as an assistant physician at the Anstalt Burgholzli, Zurich.

While in Switzerland, he met with members of the Jungian school of analytical psychology . . . acquire the patina of a cosmopolite that . . . riched progressively ever since. He . . . his European experience—especially . . . Thomas Mann—as a unique opportuni. . . . his eyes to the world outside of Philade . . . Pennsylvania Hospital. It was rounded o . . . ly rich and stimulating experience as a . . . Dr. Kinnier Wilson's service at the Nat . . . Queens Square, London. While there, . . . draughts of the best of British medicine . . . nonce being unconcerned about the . . . ceived from Dr. Earl Bond an invitatio . . . the Pennsylvania Hospital as Clinical D . . .

THE PHILADELPHIA YEARS

Equipped as he was with the panache . . . fellowship at age 36, Frank's candidacy . . . ademia was complete. His mentors, D . . . Strecker, Appel, and Palmer, saw to tha . . . his place was reserved, first as an appren . . . of a number of "footstools" in the grove . . . en route to what was destined to be a cer . . . of professorial chairs. In short order he . . . an Instructor in Psychiatry at the Unive . . . sylvania Medical School, an Assistant P . . . graduate school and an Associate Pro . . . Women's Medical College, a Visiting Le . . . normal Psychology at Swarthmore Colle . . . Lecturer in Abnormal Psychology at . . . lege, and a psychiatrist on the staffs of s . . . phia hospitals.

The next few years were equally head . . . met, wooed, and married a Main Li . . . nurse's uniform—Hope Jenkins; he beca . . . Diplomate in Psychiatry; he was an act . . . Naval Reserve Medical Group; and he . . . join the private practice at the recent y . . . of the Pennsylvania Hospital and em . . . was planned as a progressive elevation . . . Philadelphia psychiatry. His place in . . . was further assured by his election to the . . . delphia College of Physicians. He rece . . . colade when he became chief of a te . . . the prestigious Philadelphia General . . . Blockley).

As Thomas Wolfe ruefully noted, "... home again." Philadelphia was not for . . . was not to be the life that would stay cert . . . niche no matter what the rewards. He . . . be Dean of the School of Medicine and . . . Psychiatry at Loyola University in Chica . . . was tempting; he was needed, and he fo . . . lenge irresistible.

At a superficial level, he rationalized h . . . Institute by recognizing that the Inst . . . breeding ground for the exportation of its . . . chiatry to the hinterlands. He would be . . .

Philadelphia's emissaries. But Hope and Frank, as well as their many friends, found the departure from Philadelphia a wrenching experience. Their leaving tore deep affective roots. They found a measure of solace in the belief that, after all, Chicago was just a bit beyond West Philadelphia's 69th Street!

Chicago—its medical and university communities—welcomed them with open arms. Its "organized" medicine in the years before World War II was in fact a loosely knit enclave of independent fiefdoms. Coming from Philadelphia with its own boundary problems, Frank found this state of affairs quite familiar. Before he became a dean, he had been and still was a clinical psychiatrist, accustomed to dealing with resistance in all shapes, forms, and guises. This expertise stood him in good stead. In the relatively brief time he remained in Chicago, he succeeded in leaving his unique mark. But his long-term plans for Loyola had to give way to a higher priority—World War II.

ACTIVE DUTY IN THE NAVY

As a Naval Reserve officer as well as a medical school dean, Frank Braceland was a natural to recruit physicians for the Medical Corps of the U.S. Navy. Lt. Commander Braceland MC, USNR, was assigned the duties of Special Assistant to the Surgeon General, U.S. Navy, in 1942. His first job was to solicit physicians to volunteer for active duty. Ultimately, the assignment was formalized when he was ordered to report to the Personnel Office of BuMed; this required a move to Washington, D.C. (His next formal appearance in Chicago was in the 1960s to receive an honorary degree from Northwestern University. Later, Loyola University, Stritch School of Medicine, awarded him the Stritch Medal.

Frank Braceland in Washington was beset by ambivalence. He was frustrated by being kept chairborne, figuratively chained to a desk during years of active duty in the Bureau of Medicine and Surgery. On the other hand, when he became Chief of the Neuropsychiatry Branch he was finally in his element. In retrospect, he sees this assignment as King Henry V saw Agincourt on Saint Crispin's day: "He which hath no stomach to this fight, / Let him depart; his passport shall be made, / And crowns for convoy put into his purse: / We would not die in that man's company / That fears his fellowship to die with us." Frank Braceland, with Bill Menninger in the Army, Bob Felix in the Public Health Service, Don Hastings in the Air Force, Dan Blain in the Coast Guard-Merchant Marine, and their associates ("shall be remembered,/ We few, we happy few, we band of brothers") were responsible for the organization of the nation's psychiatric services during World War II.

Frank's special contribution to the naval war effort was the unique accomplishment of humanizing a military organization that prided itself on its tradition of iron men and wooden ships. Frank's approach to the old salts of the line—Navy admirals and Marine generals—was pragmatic. If they required, as their motto had it, to keep as many men at as many guns for as many days as possible, they would have to concede a little expertise to the Neuropsychiatry Branch of BuMed. Mirabile dictu! They did, and Frank Braceland was authorized to institute what amounted to far-reaching reforms in the selection of personnel in the Naval Training Stations as well as in the care, treatment, and discharge from hospitals of the Navy's psychiatric casualties. His Legion of Merit and promotion to Rear Admiral are testament to the acknowledgment by superiors of his meritorious contributions.

THE MAYO CLINIC

As trying as those years were, they actually served as a second apprenticeship at age 46 for what was to come following Frank's discharge from active duty. Not for long was he without an equally challenging billet. The Mayo Clinic had for years eschewed the creation of a Section of Psychiatry. The reason was said to be that the Doctors Mayo were as mindful of the limited facilities available in Rochester, Minn., in the prewar years as they were conscious of the magnitude of the psychiatric problems in the population their clinic served. Their successors were also aware of the changes that were taking place in the delivery of medical services.

Frances Braceland, M.D., now a civilian, was invited to join the staff of the Mayo Clinic as a member of the new Section of Neurology and Psychiatry. The initial affiliation with neurology was intended to make use of the established reputation of the distinguished and respected neurologists as the thin edge of the wedge to accommodate an Auslander.

In short order, the innovations for which F.J.B. is noted began to appear. He convinced the Sisters of St. Francis, who operate St. Marys Hospital, that as a general hospital purporting to render comprehensive services it needed a defined and separate psychiatric unit. He collaborated with the Section of Pediatrics in the establishment of the Rochester Child Health Project, for which he recruited Adelaide Johnson and Ben Spock, the latter recently released from active duty as a Navy psychiatrist. Frank established a liaison-consultation service in both the clinic and its affiliated hospitals. He persuaded the Mayo Graduate School to assign fellows (residents) in internal medicine, neurology, and neurosurgery to the Section of Psychiatry for a three-month full-time stint. In addition, he carried a full schedule of clinical responsibilities.

As an extracurricular activity, he extended his support to both the local and state communities and was involved in the exposé of the Minnesota state hospital problems. In undertaking these community actions, he launched another long and illustrious career as a mem-

ber, officer, national and international consultant, and adviser to myriad professional and governmental organizations—at last count, the number he has served over the past 38 years was 184.

THE INSTITUTE OF LIVING

Frank Braceland's appointment in April 1951 as Psychiatrist-in-Chief of the Institute of Living, Hartford, Conn., was noted, in proper Navy parlance, as "A New Helmsman Comes Aboard" in a chapter of a book celebrating the sesquicentennial anniversary in May 1972 of the founding of the Institute (3). The death of his predecessor, Dr. C.G. Burlingame, 12 months previously had left Eli Todd's Hartford Retreat adrift without a rudder. After a few stormy months the patients, the staff, the City of Hartford, and the State of Connecticut became aware that the Institute was again on the course set by Dr. Todd on May 22, 1822; a man of equal national stature, far-reaching vision, and a gentle but firm hand was now in charge. Although Frank stepped down as Psychiatrist-in-Chief in 1965, he continues on as Senior Consultant, maintaining the indefatigable pace that had helped make the Institute the exemplar of a comprehensive mental hospital. Emerson's observation that "an institution is the lengthened shadow of one man" is realized in the lasting foundation on which others have built and limns Braceland and his vision of the place of psychiatry in and of the community.

"A MAN OF PARTS"

Last year was a Braceland typical. In addition to his biweekly trips to Washington, "the mendicant" (as he calls himself) continued an enormously successful money-raising campaign in behalf of the Institute of Living's rebuilding program. He was requested to write nine papers during the year. He winnowed numerous invitations and finally consented to present 15 formal lectures; among the institutions were seven colleges here and in Canada. In what he extravagantly calls his "spare time," he reviewed books for no less than 23 journals that ran the gamut from the *New England Journal of Medicine* and *Science* to the *Psychoanalytic Quarterly* and *Theological Studies*. Verily, the man Braceland is a man of parts.

Frank is an inveterate idealist. Every place he has ever worked is the best of all places. He is nostalgic about each of them and talks longingly about his earnest desire to return—but he never has. Instead, he goes on to other challenges, leaving in his wake lasting ties of friendship and sincere regrets, both his and theirs. Each of the places he has left is much the better for his having "tarried awhile in their midst," as he would put it. Each of these places became his home. A close friend once remarked that Frank Braceland's alter ego must be that mythical Nigerian go[at] ue has his feet point forward while his he[ad] look back to where he has been.

In the years I have known him, o[nly] seen him come close to losing his compos[ure] during his tenure as Secretary of the A[m] of Psychiatry and Neurology. The holde[r] is pestered by trivia and inundated [with] Frank and his long-time friend David Boy[d] job to that of a cross between a servant a[nd] boy (4). On the day Frank came close [to] cool, he was at his desk in the Board o[ffice] scientious secretary, Clarice Johnso[n] screened the numerous phone calls to a[llow] to do what only the boss could do. A fre[e] sistent caller was giving her a particula[r] demanding a positive answer to a series [of] she had said repeatedly were not with[in] tary's power to answer. In desperation, [she] Frank and asked, "What shall I tell him [to] pursed his lips, paused (I suppose to [collect] and then replied, "Tell him to walk cast [and] floats."

Frank and David Boyd wrote a delig[htful] the trials and tribulations of being Se[cre]tary Board (4). I am sure of Frank's hand in [choosing] its Latin subtitle: "Apologia Pro Vita Su[a]" only to the redoubtable Robert Burton, [the] author of medical treatises who so de[lighted] quote Latin—phrases, aphorisms, vacet[iae].

Frank's close friends are privileged to [share] pose. He would describe himself as "[a] gentleman who loves to walk beaches." [Let] him regale congenial listeners by the ho[ur] shady, uproarious shaggy-dog stories [or] deliberately, his special brand of Nav[y] "with-a-twist-with rocks-if-you-please." days (and on occasion now) he would, i[n] into a soft-shoe routine à la Ray Bolge[r] ly older ladies who "knew him when." choice as a dancing partner for a fast [one] when he can convince the orchestra to [play] for Two."

Not the least of his talents, one for w[hich] membered with great affection as "Un[cle] incomparable prestidigitator," is his [ex]pertise is able to leave young children slack-j[aw] ment when, with a flourish of an empty h[and] to extract a coin from their ears or pock[ets]. And what is more, make it move over [their] fingers "by magic." Frank mimes W.C. [Fields] fection in pretending to be all thumbs w[hile] with one of his young grandchildren in [the] diapering. And yet, if asked, he proudly [has] latest snapshots of every one of them fr[om] pocket wallet.

The real key to Frank Braceland's pers[onal] ing optimism is his passionate religious c[onvic]tion. is devout. His wife, Hope, who is equa[lly] tously captured the essence of the man [in]

this way: "His early rising, his respects to and chats with his Maker betray his acceptance of what is, and his trust and faith in what can be, and what can be done 'with a little bit of luck' and with a little bit of help."

George Raines, an old Navy shipmate, feigning incredulity, used to say: "You can't ever follow the Dean through a revolving door for he is sure to come out after you. He's just got to be last!" Frank said it indirectly through the words of the poet Terence: "Humani nil a me alienum puto." Significantly, this was the last sentence of his Presidential Address to the 113th annual meeting of the Association in Chicago, Ill., in May 1957.

Francis J. Braceland, the Editor—The Music Will Play On

BY EVELYN S. MYERS, M.A.

IN APRIL 1977 Dr. Francis J. Braceland wrote Dr. Robert W. Gibson, then APA President, requesting that a search committee be appointed to find a new Editor of the *American Journal of Psychiatry*. In his letter to Dr. Gibson, Dr. Braceland observed that the *Journal* was going along very well. "Why, then, am I leaving?" he asked. "Only one reason: I shall be nearly 78 by the time my replacement arrives. . . . Samuel Johnson said, 'At 77 it is time for a man to be in earnest,' and besides, there are a number of things I still want to do. . . . Two thoughts play around in my mind. The first is that 'it is hard to go home while the music is still playing.' But this is cancelled out by a line from the bard: 'Reluctant lags the veteran on the stage.' "

The many letters received after Dr. Braceland's decision was reported to the Board of Trustees and in *Psychiatric News* reflect in some measure how he is regarded inside and outside of psychiatry. Some of the letters touch on traits and characteristics that have made him an outstanding Editor. From the vantage of an association with Dr. Braceland that spans the entire 13 years of his editorship, I would like to quote and comment on extracts from a few of those letters.

A former member of the *Journal*'s Editorial Board wrote

> In a very real sense your decision marks the end of an era, probably one of the most dramatic chapters in the history of our culture. . . . You are fortunate in being able to age gracefully and to leave the arena upright and with dignity. None of us could hope for more.

The strong sense of history implied in these sentences has been a characteristic of the Braceland editorship. We on the staff who met with him each time he came to Washington on his biweekly trips from Hartford became keenly aware of this as, meeting with us, he mused on how to solve a knotty editorial problem. Often he would reach back to the days when he was a resident at the Pennsylvania Hospital, when some of the somatic treatments were being applied to psychiatric patients for the first time; or to the days when as a Rockefeller Fellow he was learning from Jung at the Bürgholzli in Switzerland; or when, during World War II, he worked hard to educate the Navy "brass" about the need for a humane approach to young sailors with psychiatric problems. Dr. Braceland's ultimate decision about whether to accept or reject a manuscript was based on criteria that met the needs of the 1970s—Is this new and important? His decision was always tempered with knowledge of what had gone on before.

Another side of Dr. Braceland's personality came through in a letter from the editor of a literary magazine:

> Few privileges in this world are more welcome (to me) than the discovery of a well-turned phrase, a philosophy of medicine, your approach, and a sense of humor.

His sense of humor is of course one for which Dr. Braceland is famous. One can appreciate this trait when one is in his presence at a table of guests at dinners where he has been the honoree or after-dinner speaker can attest. We staff members have been treated to a goodly measure of his famous-world-figure jokes, and an assortment of stories that defy categorizaton. The readers of the *Journal* have not had the same opportunity to enjoy his occasional response to a letter to the Editor that called for a well-turned phrase. For example, a letter in the February 1971 issue took Dr. Braceland to task for his "In his plea for shorter papers for our *Journal*, F.J.B. wrote, 'But psychiatrists who want to publish in our journal will simply have to condense their productions and write more succinctly.' Couldn't F.J.B. have given us a more succinct example, such as, 'But psychiatrists who want to publish in our journal will have to write more briefly.' F.J.B.'s response was pure Braceland: 'Our Editor, already dehydrated, hence forced to succincts and discard his briefs.' "

In a quite different vein, Dr. Braceland was especially pleased to receive a letter from a psychiatrist who, shortly after Dr. Braceland took office, had objected to the way his manuscript had been handled. Looking back on his attitude at the time and expressing his regret, the psychiatrist wrote that he "admired, very much, the excellent job you have done as editor, and I don't have to tell you how difficult your job was." The details of what had happened with the manuscript are unimportant—what is important—and what I think the psychiatrist was pleased to say in his letter—was a recognition that his manuscript had been given a fair hearing in relation to its merit.

This quality—fairness—has been a hallmark of Dr. Braceland's editorship that I

Ms. Myers is Managing Editor of the *American Journal of Psychiatry*.

0002-953X/78/0007-0789$0.40 © 1978 American Psychiatric Association

most. In evaluating manuscripts he has bent over backward to ensure that a decision was based not on bias or on his own special interests but on informed judgment. This sometimes meant asking another member of the Editorial Board to share in the final decision if a paper under consideration reflected a point of view with which Dr. Braceland disagreed. It sometimes meant reconsidering his decision to reject a manuscript when the author presented cogent arguments at variance with the comments of the experts who reviewed the paper. He also tried—even when he found it necessary to reject their papers—to encourage neophyte authors, often sending them lengthy suggestions so that they would have a better chance the next time.

KEEPING UP WITH THE TIMES

A professor and chairman of a department of psychiatry wrote Dr. Braceland:

> You have left a significant mark on the *American Journal of Psychiatry,* which has grown, during your tenure, to a genuinely stimulating publication that compares favorably with any superior journal in our own or any other specialty. Some of the heightened interest, of course, is a reflection of the exciting new research that has recently shed new light on old psychiatric syndromes. The changes in style, format, and organization and the new features which you have introduced, however, are the factors that make this journal the one which I await each month with eager anticipation.

What comes through here is a reflection of Dr. Braceland's willingness to keep up with the times. Basically a conservative person (one of his favorite expressions is, "Go not from the troubles you know to the troubles you know not of"), he has been willing to accept change when he was convinced that change was warranted. This applied to format, type style, size of the *Journal,* and the introduction of such features as special sections and topical groups of papers devoted to a subject of importance, overview and other special lead articles, and, more recently, our new Clinical and Research Reports section. He has wanted the *Journal* to be as good as possible, and he has given thoughtful consideration to all suggestions for change, whether they came from an author, a member of the staff, an Association member he met on one of his frequent trips around the country, or anyone else who had something to say. The *Journal* has never been far from his thoughts. Reading manuscripts on planes, at home in the evenings and on most weekends, and during his so-called "vacations"—this has been his way of life for the past 13 years. I have never known a person who has been more dedicated to his job than Dr. Braceland.

The final quote, which refers back to Dr. Braceland's letter to Dr. Gibson, needs no comment from me. From a current member of our Editorial Board, it says it all:

> You are more than entitled to do the reading and other things you want to do without worrying that thousands of psychiatrists will be mad at you for not continuing to take care of us! But you have spent a marvelous lifetime preparing us to negotiate our selfishness. By all means go home while the music is playing—it will play forever for you.

These letters are a testament to some of Dr. Braceland's better-known qualities. I would also like to touch on one or two other qualities that have particularly impressed me.

The first is pride—pride in being a physician and especially a psychiatrist. This is a pride associated not with arrogance but with the possibilities of service to one's fellow man. Dr. Braceland has been pleased in recent years—and this has permeated his writings—that psychiatry has moved closer to the rest of medicine. He sees psychiatry's principal mission as taking care of the mentally ill. The "medical model" means different things to different people; to Dr. Braceland, if my perception is correct, it means the well-trained, compassionate physician putting the needs of the patient before all else. In selecting material for the *Journal* he has kept uppermost in his mind: Will this help psychiatrists with their patients?

His pride has a wry twist. He is understandably proud of the honors his beloved profession has bestowed on him—head of the Navy's Neuropsychiatric Branch during World War II, Secretary of the American Board of Psychiatry and Neurology, President of the American Psychiatric Association, and, most recently, Editor of APA's official journal. But there is another side. "I'm always afraid when I'm introduced to a psychiatrist for the first time," he has been known to say, "that I may have sent him as a young medical officer to Attu, or signed the letter telling him he failed his Boards, or rejected one of his brainchildren."

"Rejecting brainchildren" brings me to another of Dr. Braceland's qualities as Editor. The *Journal* can accept fewer than a quarter of the articles submitted to it. For Dr. Braceland, some decisions to reject—when the paper was clearly below standard—were not difficult. But others brought agony. His concern was not so much the fear of losing a good article (rejected authors sometimes sent him a reprint of their article when it was published elsewhere and this pleased him) as concern over the author's wounded feelings. Many authors received special letters from Dr. Braceland rather than the form letters a large journal is often obliged to use. These letters reflected the Editor's character—his charm, wit, and compassion. They also transmitted his genuine regret, and a number of authors have written him to say, "That was the nicest rejection I ever received."

Finally, a more personal note. When Dr. Braceland and I began working on the *Journal* 13 years ago, neither of us knew quite what to expect of the other. The relationship—and I think this is true with most important relationships—took a while to develop to a point

where we were both comfortable with it. Part of the reason for its success was that we both were committed to do the best job possible, and each of us respected that commitment in the other. But also of great importance was Dr. Braceland's extraordinary (uncanny, almost) sensitivity to the feelings of those within his orbit. Within two minutes of his walking into the *Journal* office on his visits from Hartford he could tell how things were going with us on the editorial staff, and if there was a problem he offered his assistance in solving it. The other members of the staff did not only have respected Dr. Braceland as a distinguished Editor but have come to love him as a kind and sensitive human being.

One could search *Bartlett* and discover a quotation that might capture some of Dr. Braceland's special qualities. I prefer a verse from Proverbs:

> Wisdom is the principal thing, therefore get wisdom.
> Yea, with all thy getting, get understanding.

Discriminating Features of Borderline Patients

BY JOHN G. GUNDERSON, M.D., AND JONATHAN E. KOLB, M.D.

Borderline patients were compared with schizophrenic patients, neurotic depressed patients, and a group of patients with differing diagnoses. The purpose of this comparison was to find out whether borderline patients could be discriminated from other psychopathological groups and whether a discrete list of recognizable characteristics discriminating borderline patients could be isolated. According to the results of the comparison, borderline patients can be discriminated with high accuracy from matched comparison groups with whom diagnostic confusion is common. Seven criteria provided a clinically sensible and practical means of approaching the diagnosis of borderline disorder.

THE FIRST STEP in defining a clinical syndrome is to demonstrate that it is a recognizable entity that can be discriminated from other disorders. This is particularly relevant to borderline disorder because of its presumed position between psychosis and neurosis and the arguments that persist as to whether it is really a subtype of schizophrenia or a variant of affective disorder. In a previous report (1) the descriptive literature on borderline patients was reviewed and those characteristics of borderline patients about which there is consensus were summarized. We have also demonstrated which of those consensus characteristics were actually found and which were not found in a systematic study (2). In this report we ask two new questions. First, can borderline patients be discriminated from other psychopathological groups with whom diagnostic confusion often exists? The failure to do so would cast doubt on the rationale for continuing use of borderline disorder as a separate diagnostic entity in our clinical parlance. A positive result could lend support to the inclusion of borderline disorder in our standard nomenclature. The second question addressed in this study is, Can a discrete list of readily recognizable characteristics that are highly discriminating be isolated? Such a list could be useful in selecting a sample of borderline patients in a replicable way.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Gunderson is Assistant Professor, Department of Psychiatry, and Dr. Kolb is Instructor in Psychiatry, Harvard Medical School, Boston, Mass. Dr. Gunderson and Dr. Kolb are also Assistant Psychiatrists, McLean Hospital, 115 Mill St., Belmont, Mass. 02138.

The authors wish to acknowledge the statistical assistance of Murray Dalziel.

METHOD

All of the patients included in this study were given clinical diagnoses by the admitting physician at McLean Hospital. All of the patients were hospitalized, were between the ages of 16 and 35, and had no evidence of organicity. Only patients given an initial diagnosis that was considered certain for schizophrenia, neurotic depression, or borderline personality were included. Patients given a primary diagnosis of alcoholism or drug habituation, even if they were considered to have a borderline personality organization, were not included. Each sample was further screened using independent research criteria and/or clinical diagnoses to prevent overlapping diagnoses (3). The samples were matched for age, sex, race, and marital status (2) (see table 1). The patients were generally young, white, middle-class people from the Boston area; approximately two-thirds of them were women.

After giving informed consent, the 64 patients were interviewed within one week of admission using the Diagnostic Interview for Borderlines (DIBs). The DIBs consists of 123 inquiries ("items"), from which 29 of the characteristics of borderline patients found in the literature (each presented as a "statement") are scored. These statements are distributed in the 5 areas ("sections") of the interview as follows: 4 for social adaptation, 5 for impulse/action patterns, 5 for affects, 8 for psychosis, and 7 for interpersonal relations. The statements are added and converted into a scaled score for each of these 5 sections. Reliability and scoring characteristics of this instrument have been reported elsewhere (4).

A stepwise discriminant function analysis was used to compare the borderline sample (N=31) with three different comparison groups.[1] The first comparison group was composed of 22 schizophrenic patients. The second comparison group was composed of 11 patients with neurotic depression. The third comparison group, called "all others," consisted of a combination of the schizophrenic and neurotic depressed patients plus a

[1]This method uses Rao's V to indicate the separation between groups. The first variable entered is one that maximizes V. This proceeds sequentially unless the variable correlates highly with all other variables in the function. In that case the V will decline and that variable is excluded.

mixed group of 9 patients with other diagnoses. For each of these three comparisons discriminant functions were done on two sets of variables. The first discriminant function was done on the 29 summarizing statements. The second analysis was a discriminant function using the scores from each of the 5 sections of the interview. One further discriminant function analysis was done on the comparison between the borderline patients and all others. This function was done on 10 items selected because we have found them especially helpful in our clinical experience. Other reasons for selecting these items were that they reflected independent areas of function and were among the most significantly discriminating according to t tests. The best overall discriminators were then synthesized on the basis of clinical and conceptual overlap into a discrete list of clinically sensible discriminating characteristics.

RESULTS

The borderline patients were first compared with the schizophrenic patients, then with the neurotic depressed patients, and then with the group of patients with differing diagnoses.

Borderline Versus Schizophrenic Patients

Together, the 8 statement variables listed in table 2 were able to discriminate the borderline sample from the sample of schizophrenic patients with 100% accuracy. The most useful discriminator was flat affect. It was unusual to find flatness in our borderline sample, but it was common in the schizophrenic patients. This difference was more obvious in terms of affect within the interview than as it was reported in the patients' recent histories. As found previously (5, 6), although schizophrenic patients actually evidenced considerable depression and reported recent histories of other affects, unlike borderline patients they were often flat at the time of the interview.

The variable of devaluation/manipulation reflects qualities of the close interpersonal relationships of borderline patients that are less evident in schizophrenic patients. In fact, as the "loner" variable in-

For the DIBs sections, Wilks' Lambda was .537, the group centroid for the borderline patients was .790, and the group centroid for all of the other patients was −.578.
**A low score on this variable was expected to characterize borderline patients.
***This variable was higher in the comparison group (i.e., not in the expected direction).

borderline patients reported more frequent and sustained dysphoria and anhedonia. Borderline patients were more frequently found to have a sexually deviant pattern (usually promiscuity) or antisocial pattern, and they had lower school or work achievement records. Borderline patients were more intolerant of being alone, but their interpersonal relations were more unstable and marked by more devaluation and manipulation. Such problems were often evident in their previous treatment experiences, which indicated countertransference problems, staff splitting, and frequent reports of "getting worse." A final major area of difference is that the borderline patients were more likely to report brief paranoid experiences and occasionally had experiences that resembled hallucinations but proved difficult to evaluate. The neurotic depressed patients were more likely to have had possible manic episodes.

With respect to the section scores (see table 3), once again more enduring patterns (impulse/action patterns and interpersonal relations) proved more valuable than signs and symptoms. The section scores discriminated the two groups of patients with 84.09% accuracy. Neither social adaptation nor affects added much when the other three sections were taken into consideration.

Borderline Patients Versus All Others

The comparison between borderline patients and all of the other patients sharpened the focus on those characteristics of borderline patients which are the best overall discriminators for use in a variety of differential diagnostic problems. The 14 DIBs statements shown in table 4 were able to discriminate the borderline patients from all other patient groups with 86.84% accuracy.[2] Because of clinical and conceptual overlaps within the 14 variables they can be condensed into the following 7 criteria:

1. *Low achievement.* The typical level of the school and work achievement in the two years before hospitalization was quite low in borderline patients. This was so despite apparent talent or ability to do better and was quite similar to the achievement levels attained by schizophrenic patients.
2. *Impulsivity.* The principal form this took was a pattern of serious alcohol or drug abuse. Sexual deviance was highly related to impulsivity because it consisted largely of the promiscuous behavior of borderline patients under the influence of alcohol or other drugs.
3. *Manipulative suicide.* This refers to those suicide efforts or gestures which seemed designed to exact a "saving" response from a significant other. This commonly occurred as wrist slashing or overdosing and was the most frequent precipitant for hospitalization.
4. *Heightened affectivity.* Borderline patients dis-

[2]Application of this function to an additional independent sample of 29 clinically diagnosed borderline patients accurately identified 76%. In another analysis, 81% of 27 patients who were classified by this function as having borderline disorder had been given this clinical diagnosis.

played multiple intense affects. Anger may be the most discriminating of these. Even more important in discriminating borderline patients from others was the absence of flat affect and the relative absence of satisfied feelings.

5. Mild psychotic experiences. These most commonly took the form of drug-free paranoid ideation, derealization experiences, and a history of regressions or getting worse in previous treatment. Occurrence of any of these in the absence of severe widespread psychotic symptoms of any type in the patient's past life was a strong indicator for the borderline diagnosis.

6. High socialization. Borderline patients were definitely not socially isolated ("loners") and were, in fact, intolerant of being alone, i.e., compulsively social.

7. Disturbed close relationships. Devaluation, manipulation, dependency, and masochism characterized and caused instability in the intense attachments of borderline patients. Devaluation refers to the tendency to discredit or undermine the strengths and personal significance of important others. Manipulation is used here to describe those efforts by which covert means were used to control or gain support from significant others. Some typical ways included somatic complaints, provocative actions, or misleading messages. Masochism refers to the pattern in which borderline patients repeatedly, knowingly, and avoidably found themselves hurt in their close relationships (i.e., they saw themselves as victimized). The dependency issues of borderline patients were frequently manifest in receiving actual caregiving or directions from their important other.

A discriminant function by section scores showed that for this comparison all 5 areas provided valuable discriminatory information (see table 4). The section scores discriminated the patient groups with 81.58% accuracy. As in the previous comparisons, sign and symptom areas (psychosis and affects) were less helpful than the impulse/action patterns and interpersonal relations.

The third function on this comparison was derived from 10 highly specific items that had shown differences on t tests. The 7 items included in the function are shown in table 5 in the form in which they are asked on the DIBs. This function discriminated the borderline patients from all others with 85.35% accuracy. This is very similar to the function that was derived from statements. Sadism reflected a habitual pattern of being hurtful in relationships despite conscious knowledge of the effect. Two other items had to do with the fact that the delusions reported by borderline patients were circumscribed and ego alien (patients felt disturbed about them, i.e., they were experienced as symptoms). Loneliness and emptiness were very frequent complaints and quite specific to the borderline patients. Another useful discriminator was the frequency with which borderline patients reported having formed special relationships with previous therapists or others in caregiving positions. Other items that resembled aspects of the previous functic history of self-mutilation and drug depe

DISCUSSION

This study has shown that borderline discriminated with high accuracy from parison groups with whom diagnostic common. The fact that there were fewe with slightly higher power for discrim line patients from schizophrenic patie neurotic depressed patients may reflec the diagnosis of neurotic depression is more difficult differential diagnosis. If s apply only to hospitalized neurotic depre who are a much more disturbed gr hospitalized neurotic patients.

The advantage of a list of the best ov nators developed from items over one de statements is that the items are more dis pler to evaluate or quantify. The list derived from the statements was conde teria that provided a clinically sensible means of approaching the diagnosis of order. These have the advantage of bei ly applicable and conceptually enlighte

Two unresolved questions about this degree to which the discriminating va this study are generalizable to other set diagnostic habits may differ and to wh would hold up if other comparison gr ployed. A potentially more difficult would be one made up of patients with orders not considered borderline. Even ing would be to examine a sample fro

admissions or a cross-section of the general population.

There are several ways in which we foresee these results can be used. The acceptance of a reasonable and replicable approach to the use of the term "borderline" can help clinicians anticipate certain clinical problems and subtypes. Among these are the probable contraindications for unmodified psychoanalytic treatment (7, 8), the questionable advisability of antipsychotic medications (9), the risks of staff splits (10), and the temptation to underestimate or overestimate the patient's potential level of functioning. A major implication of several of the recent reports (5, 11) on the social functioning of borderline patients also targets the low level of work and school achievement as a major problem for such patients and points to the role that social learning programs (groups, rehabilitation, milieu) can have in comprehensive treatment planning.

A second advantage of a practical and replicable guide for diagnosing borderline patients is that it would allow research to proceed into questions whose answers are controversial or unknown. Among these questions are the following: 1) Are borderline patients a heterogeneous group containing subgroups that could more appropriately be placed in other standard diagnostic categories? 2) Do borderline patients have common genetic linkages with chronic schizophrenic patients, as suggested by the adoptive studies (12)? 3) Do formulations employing splitting and projective identification as the predominant defenses (13) or abandonment depression (14) reflect our understanding of these patients; or, as others have suggested, are different formulations required (15)? 4) Do these patients have specific psychopharmacological sensitivity to antidepressants or lithium (9)? 5) Is an expressive supportive psychotherapeutic approach (16) preferable to a more limited ego-directed approach (7, 17)? 6) Are there characteristic interactional patterns or parental psychopathology in the families from which these patients originate? 7) Does the course of these patients parallel that of schizophrenic patients (5, 11)? 8) Do the children of patients designated borderline by these criteria have a high risk for growing up to be chronic schizophrenics (18, p. 25; 19)?

These results provide evidence supporting those clinicians who have argued that borderline patients have a recognizable personality disorder. As Grinker and associates (20, 21) have shown, these results also indicate that a definite syndrome exists. The results clarify what the most discriminating aspects of that syndrome are and provide a replicable means for identifying borderline patients. Further studies that use these criteria are under way to search for external validators in terms of treatment responsivity, course, and etiology; such studies could further establish this syndrome as a coherent psychiatric disorder.

Personality and the Prediction of Long-Term Outcome of Depression

BY MYRNA M. WEISSMAN, PH.D., BRIGITTE A. PRUSOFF, M.P.H., AND GERALD L. KLERMAN, M.D.

In a follow-up study of 150 women who had undergone treatment on an outpatient basis for acute depression, it was found that the most important predictor of their long-term clinical outcome (8, 20, and 48 months after the acute episode) was personality as measured by the Neuroticism Scale of the Maudsley Personality Inventory (MPI-N). Age, race, social class, marital status, religion, number of previous depressions or suicide attempts, diagnosis, history of early deaths of or separations from significant others, history of neurotic traits as a child, amount and type of stress in the 6 months before onset, and severity and pattern of pretreatment symptoms were not predictive of outcome.

ALTHOUGH CLINICIANS and psychotherapists have long emphasized personality as a major variable in case discussions and theoretical discourse, personality measures usually have not been included as predictors of long-term outcome of depression. Most of the studies of depressive disorder that attempt to predict long-term outcome focus on the patient's pretreatment severity or patterns of symptoms or on diagnostic subtypes (e.g., the psychotic-neurotic, endogenous-reactive, or primary-secondary distinctions). A recent unpublished review of these studies by Shapiro and Klerman,[1] which distinguished between long- and short-term outcome, found few predicte

signed to weekly individual psychotherapy. All patients continued to receive amitriptyline for a transitional phase of 2 or more months and were then further randomized into one of three drug procedures. Within each contact group, one-third of the patients continued on amitriptyline, one-third were withdrawn double-blind onto placebo, and one-third were overtly withdrawn from medication. Treatment continued in these six treatment groups for a further 6 months, a total of 8 months, and then ended. Patients were then no longer under the direct clinical responsibility of the two research clinics.

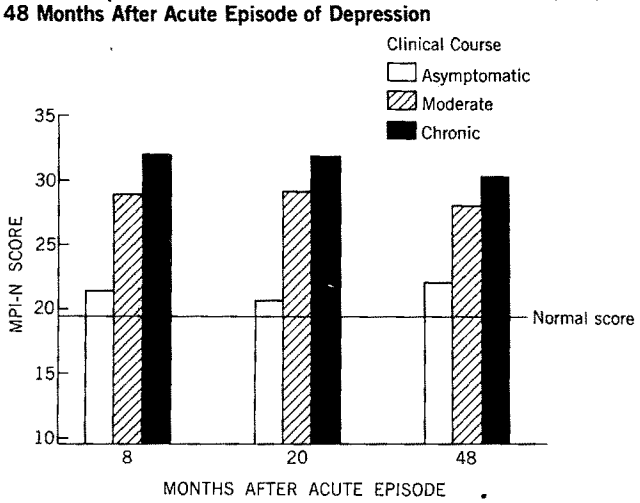
Follow-Up

Twenty and 48 months after maintenance treatment had ended the patients were again located and interviewed. A psychiatrist and a research assistant reviewed with the patients their clinical course and treatment experience since the previous contact. At 20 months, 149 patients were located and followed; at 48 months only the first 94 patients were followed due to the termination of the project.

Criteria for Chronicity

A crucial aspect of the follow-up study depended on assessing the patient's longitudinal clinical course and developing objective criteria for chronicity. Using the information collected at each interview, a month-by-month rating of the patients' clinical status on a 7-point global scale was reconstructed for each month during the follow-up period. On the basis of these ratings each patient received a blind assignment to one of three groups: asymptomatic, moderate, and chronic. The asymptomatic patients were almost entirely symptom free over the period assessed and never rated higher than a 2 more than 1 month out of 12. Patients with a chronic course were never asymptomatic during the period assessed and maintained a continual moderate level of symptoms (mean rating of 3). Patients who did not meet either of these criteria were assigned to the moderate group.

Personality Assessment



Personality was evaluated using the Maudsley Personality Inventory (MPI), a 48-item self-report scale developed by Eysenck in Great Britain and extensively used as a general mode of personality assessment (3–5). Two scales were derived from the MPI: the N Scale (neuroticism), which is a general index of the patient's predisposition to neurotic illness, and the E Scale, which is related to the introversion-extraversion concept and relies heavily on ideas of Jung. The MPI has been used extensively in Western Europe and the United States, particularly in research on depressed patients, where it has been shown to be related to different types of depression and to differentiate between depressed patients and other diagnostic groups.

The MPI-N was completed by the patients after 1 month of treatment, when they had shown a symptomatic response. This procedure was followed in order to minimize the effects of illness on reporting (6). Subjects were instructed to answer according to how they usually acted or felt. Appendix 1 shows a sample of items from the N and E Scales.

TABLE 1
Clinical Course of Depressed Patients 8, 20, and 48 Months After Acute Episode (in percents)

FIGURE 1
Relationship Between MPI-N Scores and Clinical Course 8, 20, and 48 Months After Acute Episode of Depression

RESULTS

Clinical Course

Table 1 presents the clinical courses of depressed patients 8, 20, and 48 months after the acute index episode. The 8-month assessment covered the previous 6 months, while the patients were on maintenance therapy. The 20-month period covers the past year since termination of maintenance treatment, and the 48-month period covers the past 2 years. We used the 2-year period because we felt that a longer time span might result in poor recall. In all three periods about one-third of the patients were in complete remission and between 12% and 30% were chronically but mildly symptomatic.

Sociodemographic, Historical, and Clinical Characteristics

Appendix 2 lists the social, historical, and clinical variables that *did not* differentiate the chronic group. The amount of stress experienced in the past 6 months was measured using the Recent Life Events Scale. The

patients' pretreatment symptoms were assessed by a modified version of the Hamilton Rating Scale for Depression, the Raskin Depression Scale, and by two self-report scales, the Inventory of Psychiatric and Somatic Complaints and the Mood Scales (1).

Personality

Of the two scores derived from the MPI, the N score for neuroticism showed a difference, but the E score did not, supporting our conclusion that our findings were not due to a halo effect or to nonspecific response set factors. Compared with the other clinical outcome groups, the chronic patients had higher neuroticism scores initially and at 8, 20, and 48 months (see figure 1). Although the differences did not reach significance in the 48-month period, the trends were in the same direction. The chronic patients were initially more neurotic. The personality scores on the N Scale at the beginning of treatment were predictive of clinical outcome. In fact, there was a gradient in that the chronic patients had the highest initial scores (all above 30). The patients who were asymptomatic had the lowest initial scores (between 21 and 23, which is close to the reported score of about 20 in normal populations). The intermediate MPI-N scores of the moderately symptomatic group were above the normal.

DISCUSSION

These findings show that personality assessment is a useful predictor of the clinical course and long-term outcome of the ambulatory nonbipolar depressed patient. The clinical significance of these findings is that patients with long-standing neurotic maladaptations as measured by the MPI-N are at risk for persisting depressive difficulties. Such patients are particularly vulnerable to poor long-term outcomes. These findings also raise methodological questions about the assessment of personality, as well as clinical questions about the relationship between personality, clinical course, and treatment.

The Assessment of Personality

The relationship between personality and depression has been discussed in the clinical literature for over five decades. Chodoff (7) reviewed the psychodynamic and interpersonal theories related to depression in 1972. Most theories emphasize the etiological relationship between personality and depression and seek personality factors that may be an antecedent to the depression. In this framework, emphasis has been placed on such factors as dependency, guilt, and hostility turned against oneself as well as general neuroticism. A second area of interest in the personality-depression relationship has been the attempt to relate personality patterns to symptom profiles in such a way that relationships have been shown between such patterns as hystericism and obsessionality (8). Relatively little attention, however, has been paid in the research literature to the role of personality as a predictor of clinical course and long-term outcome.

The Maudsley Personality Inventory, the scale used in this research, is a very broad measure designed to assess dimensions of personality, such as neuroticism, hostility, dependency, feelings of guilt, and [illegible] features, that have been identified in the literature as related to predisposition to depression. Future follow-up studies of depressive subjects should include, in addition to the MPI personality measures, some of the newer measures developed specifically for depressed patients and being tested by the staff of the Collaborative Project on the Psychobiology of Depression (9).[2]

State, Trait, Response Set

There has been controversy about the use of personality measures as assessments of trait rather than how much they merely reflect clinical state. Two questions are raised by this controversy: 1) Is personality a direct measure of severity of clinical depression? 2) Does personality assessment reflect response set?

In regard to the first question we found that severity of depressive symptoms and the presence of a previous history of depression did not predict long-term outcome, i.e., the patients who were the most sickest did not have the poorest outcome nor were patients with the most neurotic personality disturbed. Therefore, severity of depression and personality seem to be separate dimensions.

In regard to the second question, the personality measures completed 1 month after the depression still predicted outcome after 8, 20, and 48 months. Therefore, if response set was operating, it is long term and enduring. The fact that the initial scores predict outcome argues against a general response set.

Personality, Course, and Treatment

Although the detailed data are not presented here, there was suggestive evidence that personality may be influenced by treatment. As a general information of the effect of personality on treatment, multiple regression formulas were calculated for the control group and for each of the treatment groups in the maintenance study. Of interest was the fact that in the regression equation for the control group, who received neither drugs nor psychotherapy, the correlation on the MPI-N Scale but not on the E Scale was highly significant. Of the MPI-N scores had the single highest weight in the multiple regression equation. Treatment with therapy and with drugs reduced the correlation of MPI-N score with outcome, suggesting that the effect of treatment was to ameliorate the negative influence of personality variable on outcome.

[2]Hirschfield RMA, Klerman GL, Gough HG, et al. [illegible] interpersonal dependency (unpublished manuscript)

To further search for pretreatment variables that may have predicted the chronic outcome at the 20-month follow-up, we examined all patients who had been assigned to the no-maintenance-treatment group (N=50). We divided these 50 patients as to their clinical course in the follow-up: chronic (N=12) and nonchronic (N=38) (10). We compared the two groups as to social history and pretreatment clinical status. From the large pool of variables, only neuroticism as measured by the MPI-N significantly differentiated the chronic patients. The chronic patients in the no-maintenance-treatment group were more neurotic, suggesting that the "neurotic" patient who receives no maintenance therapy after an acute depression is at greater risk for developing chronicity in the subsequent months. This latter finding was not replicated after 48 months, perhaps due to the reduced sample size or the presence of other intervening factors. Therefore, it must remain speculative.

Together these findings suggest that many chronically depressed patients, who for the most part have neurotic personalities, are patients who have partially recovered from an acute episode and have mild unresolved symptoms. Moreover, these findings highlight the utility of personality assessments in the longitudinal study of depressive subjects. Future longitudinal studies of depression that emphasize prediction should include personality measures in addition to the usual symptom and diagnostic ratings, and further attention should be given to the development of personality measures that include a broad range of dimensions.

APPENDIX 1
Sample of Items from the Maudsley Personality Inventory Neuroticism and Extraversion Scale

Neuroticism Scale Items

Does your mind often wander while you are trying to concentrate?
Are you sometimes bubbling over with energy and sometimes very sluggish?
Are you often troubled about feelings of guilt?

Extraversion Scale Items

Do you usually take the initiative in making new friends?
Are you inclined to be quick and sure in your actions?
Do you prefer action to planning for action?

APPENDIX 2
Variables That Did Not Differentiate Chronic Depressed Patients from the Other Groups 8, 20, and 48 Months After Acute Episode

Age
Race
Social class
Marital status
Religion
Number of previous depressions
Number of suicide attempts
Early deaths of or separations from significant others as a child
Neurotic traits as a child
Amount and type of stress in the 6 months before onset of acute episode
Severity of pretreatment symptoms

Side Effects in the Neonate from Psychotropic Agents Excreted Through Breast-Feeding

BY JAMBUR ANANTH, M.D., M.B.B.S., D.P.M.

Neuroleptics, antidepressants, lithium, anxiolytics, and hypnotics may be excreted in breast milk. Because of the danger to the neonate, drugs such as diazepam, lithium, bromides, reserpine, and opium alkaloids should not be given to lactating women, and barbiturates, haloperidol, and penfluridol should be administered with caution. The side effects produced as a result of breast-feeding of the infant by mothers consuming psychotropic drugs are reviewed and possible preventive measures are discussed.

PSYCHOPHARMACOLOGICAL agents are used frequently during pregnancy to control nausea and vomiting and during labor for analgesic purposes, as well as after delivery for anxiety and depression. Thus they may reach infants of nursing mothers receiving these medications. Even though there are many reports of neonatal toxicity resulting from breast-feeding by mothers treated with psychopharmacological agents, no definitive answer to the problem is currently available. In this paper the available literature is reviewed with the following aims: to provide guidelines as to what drugs to avoid giving breast-feeding mothers, to point out the need to anticipate side effects and observe the baby carefully if the mother is taking any drugs, and to point out the importance of monitoring the infant carefully if the mother is taking certain drugs known to produce side effects in the neonate.

BREAST-FEEDING AND DRUG SIDE EFFECTS

Sedatives and Analgesics

Barbiturates and alcohol. The amount of barbiturates excreted in breast milk has not been found to affect the nursing infant (1). Sapeika (2) described a report of drunkenness in an 8-day-old bre
with alcohol in his blood; the mother ha
of port wine within 24 hours. Howeve
amount of alcohol ingestion by the n
does not necessarily have adverse effect

heroin) and its effect on the newborn infant, Cobrink and associates (14) found a positive correlation between the amount of the narcotic in the milk and the mothers' intake of it. Several others (2, 5, 15, 16) have reported that therapeutic doses of morphine to nursing mothers result in the excretion in the milk of small quantities of morphine that do not harm the child. However, narcotics are consumed by addicted mothers in amounts higher than therapeutic doses. With such higher doses there is always the danger of the nursling developing side effects. In one study (14), 13 of 22 breast-fed infants of mothers who had taken 2–45 mg of heroin per day were reported to have manifested withdrawal symptoms. One case report involved an infant breast-fed by a mother who became addicted to heroin after delivery. The baby showed signs of narcotic withdrawal every time the mother was deprived of the drug or whenever the drug was withheld for therapeutic reasons (17). Gradual weaning is one of the treatments proposed for such addicted infants (18). Meperidine has also been reported to be excreted in breast milk, but in quantities too small to affect the nursing child (19).

Propoxyphene. Another commonly used analgesic is propoxyphene (Darvon), which has been found to be excreted in the breast milk of animals. In one study (3) the amount of propoxyphene in the stomach of a nursing rat during the suckling period was only .04% of the total amount administered to the lactating rat. Catz and Giacoia (20) reported in a personal communication from Eli Lilly and Company that following a suicide attempt with propoxyphene by a nursing mother, the quantity of the drug in the breast milk was half the amount in the mother's plasma. A theoretical calculation based on the above shows that an infant weighing 5.4–7.3 kg could ingest up to 1 mg of the drug per day—a significant amount—if the mother were to consume the maximum recommended dose around-the-clock.

Anxiolytic Sedatives

Phenobarbital. Phenobarbital is an important member of this drug group even though it is not used as frequently as in the past. For many years it has been known that this drug is excreted through breast milk (21), and it appears that therapeutic doses of barbiturates to the nursing mother have little or no effect on the infant (2, 4–6, 15, 19). However, one questionable report of toxicity in an infant has been found in the literature (22). In contrast to these findings, Finch and Lorber (23) reported a well-documented case of toxicity involving methemoglobinemia, drowsiness, ecchymosis, and collapse in the newborn breast-fed daughter of an epileptic mother who was taking 390 mg of phenobarbitone and 400 mg of phenytoin daily. The toxicity improved with the administration of 250 mg of whole blood, recurred upon resumption of breast-feeding, and improved when donor's milk was used. In this case the side effects seemed to be fairly well established, but they cannot be attributed to phenobarbitone alone.

Although in general only quantities of barbiturates insufficient to directly affect the infant are excreted through breast milk, even these small quantities are enough to increase the activity of drug metabolizing enzymes in the liver. Phenobarbital in concentrations high enough to produce enzyme induction has been reported in animals (24). It must be stressed that the influence of inducing agents is not limited to a specific group of enzymes. In infants this increased enzyme activity may affect other drugs and substances passed through breast milk, even endogenous corticosteroids.

Diphenylhydantoin. This drug is used to treat epileptic psychiatric patients as well as nonepileptic psychiatric patients. It is excreted in the milk in limited quantities (25, 26). It is generally assumed that no side effects develop in the nursing infant (27, 28); and only one case of methemoglobinemia has been reported (23).

Benzodiazepines. Therapeutic doses of chlordiazepoxide are excreted in breast milk in quantities insufficient to affect infants (4, 19, 20), but central depression similar to that produced by diazepam has been reported (29). Diazepam, after intramuscular injection, has been reported to cross the placenta rapidly (30). The drug is not metabolized at all in the fetal liver or small intestine, and thus the infant is susceptible. Diazepam administered during labor has been reported to affect the temperature regulation of neonates (31).

Diazepam has also been reported to cross into breast milk (4, 19, 32, 33). Patrick and associates (32) described lethargy and weight loss in a nursing infant whose mother was taking diazepam. Erkkola and Kanto (33) reported that from the fourth day on, there was a remarkable decrease in the level of diazepam and its metabolites in the neonatal blood, indicating that the first four days of the neonatal period may be the most susceptible time. Furthermore, these researchers also noted that detoxification of diazepam is accomplished by its conjugation with glucuronic acid, the same mechanism by which free bilirubin is eliminated. It is possible, therefore, that if infants receive diazepam through breast milk or from other sources, physiological jaundice may be prolonged and hyperbilirubinemia may occur. Indeed, this side effect has been noted in the infants of mothers who took diazepam during labor (34). On the basis of the current evidence, it is advisable not to give diazepam to nursing mothers. Chlorazepate may cause drowsiness and should not be administered to nursing mothers, based on the manufacturer's advice (35).

Meprobamate. Concentration of this drug in breast milk is two to four times that in maternal plasma (19). Infants should be monitered for possible signs of drug intoxication during meprobamate therapy.

Beta-receptor blocking agents. Karlberg and associates (36) have indicated that propranolol is excreted freely in breast milk and the actual milk-to-plasma ratio is greater than 1:1. Hence under no circumstances

should this drug be administered to a nursing mother, and no mother taking this medication should be permitted to breast-feed her infant.

Antidepressants

Several studies (3, 4, 15) have reported that imipramine could not be found in breast milk after 5 days of administration. However, Vorherr (37) found that imipramine was excreted in breast milk and that while the drug level in plasma was .2–1.3 mg/100 ml, the drug level in milk was .1 mg. Therefore only .1% of the drug is excreted in the milk per day, and the neonate fed with breast milk should not be affected. Desipramine and amitriptyline are also not excreted in milk in appreciable quantities (4, 19). Therapeutic doses of tranylcypromine are excreted in breast milk in quantities too small to affect the child (4, 15). Therefore antidepressants of both groups can be safely given to a nursing mother. Of 103 nursing mothers who received dextroamphetamine sulfate for postpartum depression, there were no instances in which a baby showed any evidence of stimulation or insomnia (3). Attempts to demonstrate the presence of the drug in milk have not been successful (19).

Lithium. Lithium passes from maternal blood to breast milk. Infants breast-fed by women on lithium therapy do ingest a certain amount of the drug. In fact, Schou and Amdisen (38) have shown that in one sample the lithium concentration in breast milk was about half that in the nursing mothers' blood. Simultaneous measurement of the infants' serum lithium concentrations indicated that the levels were about one-half those of the mothers during the first week of life and about one-third during subsequent weeks. Based on these findings, they commented,

> Arguments can be presented both for and against the view that a lithium-treated woman should be permitted to breast-feed her child. On the one hand, during the pregnancy the child has been exposed to the same lithium concentration as the mother for many months, and it seems unlikely that exposure to a lower lithium concentration for a few more months will do any harm.

However, I feel strongly that any mother on lithium should not breast-feed her baby for the following reasons. Even though the serum lithium concentration in the infant is one-half to one-third of the mother's serum lithium level, the infant's regulatory and excretory mechanisms are not well developed; and tolerance of lithium in intrauterine life does not automatically provide proof of safety during the early extrauterine life. Other researchers (37, 39) have noted lithium levels in breast milk similar to those reported by Schou and Amdisen (38). Perhaps the findings of Tunnessen and Hertz (40) lend support for not permitting the mother on lithium to nurse her baby. They reported a breast-fed baby who had a serum lithium level of .6 mEq/liter, compared with a serum level of 1.5 mEq/liter in the mother and who manifested cyanosis and poor muscle tone. An ECG of the infant showed T-wave changes in the lateral pericardi... were compatible with drug effect.

should be aware of the potential side effects to the neonate resulting from breast-feeding.

Most drugs are excreted in the milk in small quantities, but this fact cannot be too comforting because of the possibility of cumulative effects, slow or absent detoxification, enzyme induction, and limited excretion in the neonate. In addition, even though side effects are not apparent, certain subtle behavioral problems may develop. The physician, then, has two choices. If the mother requires prolonged medication, especially with drugs known or suspected to be dangerous, she should be advised to bottle-feed her infant. If the drug ingested by the mother is not known to be dangerous, she should either be persuaded to bottle-feed or to keep strict vigilance over the infant being breast-fed. It is wise not to prescribe *any* medication to the lactating woman unless it is definitely needed.

With our present inadequate knowledge, it is difficult to prepare a list of drugs that are safe or are harmful to the breast-fed infant. However, we do know that drugs such as diazepam, lithium, bromides, reserpine, and opium alkaloids are to be avoided and that barbiturates, haloperidol, and penfluridol should be administered with caution. Finally, since our knowledge in this area is very limited, more research is needed. Taking a complete drug history and monitoring the infant for possible side effects will ensure comparative safety to the infant and perhaps throw more light on this topic. In all suspected drug-related or unexplained reactions in breast-fed infants, examination of the mother's drug history should be a priority, along with the cessation of breast-feeding, at least on a temporary basis.

Imipramine Response in Deluded Depressive Patients

BY FREDERIC QUITKIN, M.D., ARTHUR RIFKIN, M.D., AND DONALD F. KLEIN, M.D.

The authors examined how delusions and other psychotic features influenced treatment outcome with imipramine in patients with primary depression. Global improvement scores indicated that delusions or other evidence of psychosis do not contraindicate imipramine treatment. This finding does not support a recent report suggesting that deluded depressive patients should not be treated with imipramine. Possible explanations of the discrepancy between these two studies are discussed.

ALTHOUGH A HIGH PERCENTAGE of depressed patients respond favorably to antidepressants, no clear relationship between therapeutic effect and specific psychopathological features of depression has been identified. Glassman and associates (1) reported that the presence of delusions in patients with primary depression is negatively correlated with successful imipramine treatment. Furthermore, they suggested that such patients should be considered diagnostically different, that they represent a separate subgroup of primary depression for which the treatment of choice is ECT. This article elicited a correspondence in which Ziegler and associates (2) suggested that the treatment of choice for depressed delusional patients is amitriptyline. Ulett (2) recommended combined tricyclics and phenothiazines, and Glassman and associates (3) reasserted that all deluded depressed patients should be treated with ECT.

Our clinical experience suggests that the presence of delusions or other psychotic features does not contraindicate imipramine treatment of primary depressive illness. In order to test this we reexamined data from an earlier study testing the effect of imipramine in primary depressive illness.

METHOD

The sample was part of a large placebo-controlled investigation of imipramine and chlorpromazine effects done in the early 1960s. The subjects were inpatients who had failed to respond to nonsomatic hospital treatments. The study design has been presented elsewhere (4).

Data reported here are confined to those obtained from the depressed patients who were randomly assigned to imipramine or placebo. Diagnoses of depression were made by the study psychiatrist (D.F.K.) if the clinical picture consisted of dysphoric mood, persistent anhedonia, loss of interest, and other phasic depressive features. Patients with Kraepelinian features of schizophrenia or with evidence of organicity were excluded. Thirty-four patients received a diagnosis of manic-depressive, depressed type. (The concept of unipolar versus bipolar affective disorders was not prevalent at the time the diagnosis was made.) All patients would almost certainly have met the Research Diagnostic Criteria (5) for major depressive disorder. The mean age of the sample patients was 35.9; there were 12 men and 22 women.

All patients were drug-free for at least four weeks before the study. The LORR Multidimensional Scale for Rating Psychiatric Patients (MSRPP) was completed on all patients before and after the study. In addition, the Global Improvement Scale (GIS) was rated at the end of treatment by the study psychiatrist, who was unaware of which treatment the patients received. Maximum improvement was scored 15; no change, 10; and maximum deterioration, 5. Patients were randomly assigned to placebo or imipramine for a six-week period. Dosage was increased gradually to 300 mg/day on a fixed schedule.

Glassman and associates (1) did not present the specific criteria they used to define their study patients as delusional. There are no psychopathological features universally considered to be associated with the delusional or psychotic form of primary depressive illness. Therefore, we decided to first divide our sample on the basis of a preexisting factor so that as many patients as possible with evidence of psychosis could be separated from those who lacked such features. Since patients had been rated on the LORR by a blind rater, we decided to use the LORR MSRPP Factor F, Perceptual Distortion, to divide the sample into patients with and without evidence of psychosis before treatment. We selected Factor F because it was a preexisting scale and thus free of experimenter bias that might influence post hoc item selection. This decision was made before we examined the frequency distribution of baseline or final scores.

Factor F consists of the following items: implausible

Dr. Quitkin is Director, Depression Evaluation Service, Dr. Rifkin is Research Psychiatrist, and Dr. Klein is Director, Office of Research Development, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032. The authors are also Lecturers, Department of Psychiatry, Columbia University College of Physicians and Surgeons, New York, N.Y.

The authors would like to thank Dr. Rachel Gittelman-Klein for her useful suggestions in preparing this paper.

belief, belief in hallucinatory voices or visions, disorientation for people, and disturbed by hostile impulses. Of all the MSRPP factors it included the most items measuring the type of psychotic state seen in depressed patients. Patients with a positive rating on any item on the F scale were considered psychotic.

The sample was divided into four groups: 1) imipramine-treated patients with no pretreatment evidence of psychosis, 2) imipramine-treated patients with pretreatment evidence of psychosis, 3) placebo-treated patients with no pretreatment evidence of psychosis, and 4) placebo-treated patients with pretreatment evidence of psychosis. A two-way analysis of variance was performed. The hypothesis that the presence of delusions or other evidence of psychosis contraindicates the use of imipramine in depressive disorders would be supported if there was a main effect for drug as well as an appropriate interaction with pretreatment evidence of psychosis.

In an identical manner every item in the LORR MSRPP that could be considered to measure a delusion (i.e., implausible belief, conviction of persecution, belief in external control, and conviction of sinfulness) was analyzed individually using the procedure described for Factor F. We also analyzed for item combinations that seemed particularly relevant to the concept of "psychotic" depression. We believe this would allow a clinician to decide which item or combination of items contraindicates use of imipramine and which do not.

As a further test of whether delusions or other psychopathological features of the psychotic state were specifically associated with poor response to imipramine treatment, pretreatment scores on MSRPP items measuring the psychotic state were correlated with GIS scores within each drug group. Other items from the MSRPP such as depressed mood were also correlated with GIS scores to allow perspective on the extent to which other nonpsychotic features of the depressive syndrome are associated with favorable outcome.

RESULTS

Thirteen patients were randomly assigned to placebo and 21 to imipramine. The 4 placebo-treated psychotic patients (i.e., those having a positive score on any F scale items) had a mean GIS score of 10.5±.58, and the 9 placebo-treated nonpsychotic patients had a mean GIS score of 11.67±2.18. The total mean score of these 13 patients was 11.31. The 9 imipramine-treated psychotic patients had a mean GIS score of 12.56±2.79, and the 12 imipramine-treated nonpsychotic patients had a mean GIS score of 12.92±1.16. The total mean score of these 21 patients was 12.76. The total mean score of the 13 psychotic patients was 11.92; for the 21 nonpsychotic patients it was 12.88.

treated patients with no implausible belief had a mean score of 11.42±.93. The total mean score of these 13 patients was 11.31. The total mean score of the 5 patients who showed implausible belief was 13.20; for the 29 patients who showed no implausible belief it was 12.03.

An identical analysis was done dividing the sample on the basis of presence or absence of conviction of sinfulness (see table 3). The 11 imipramine-treated patients who showed conviction of sinfulness had a mean GIS score of 12.64±2.34, and the 10 imipramine-treated patients with no conviction of sinfulness had a mean score of 12.90±1.60. The total mean score of these 21 patients was 12.76. The 7 placebo-treated patients who showed conviction of sinfulness had a mean GIS score of 11.71±2.36, and the 6 placebo-treated patients with no such conviction had a mean score of 10.83±1.17. The total mean score of these 13 patients was 11.31. The total mean score for the 18 patients with a conviction of sinfulness was 12.28; for the 16 patients without this conviction it was 12.13.

The same analysis was done dividing the sample on the basis of presence or absence of conviction of persecution (see table 4). The 3 imipramine-treated patients who showed this conviction had a mean GIS score of 12.67±1.15, and the 18 imipramine-treated patients without this conviction had a mean score of 12.78±2.10. The total mean score of these 21 patients was 12.76. The 3 placebo-treated patients who showed this conviction had a mean score of 10.67±.58, and the 10 who did not had a score of 11.50±2.12. The total mean score of these 13 patients was 11.31. The total mean score of the 6 patients who showed a conviction of persecution was 11.67; for the 28 patients who did not it was 12.32.

The same analysis was done dividing the sample on the basis of presence or absence of implausible belief and/or belief in external control (see table 5). The 4 imipramine-treated patients who showed either of these beliefs had a mean GIS score of 14.0±.82, and the 17 imipramine-treated patients who showed neither belief had a mean score of 12.47±2.07. The total mean score for these 21 patients was 12.76. The 2 placebo-treated patients who showed either or both of these beliefs had a mean score of 10.50±.71, and the 11 who did not had a mean score of 11.45±2.02. The total mean score of these 13 patients was 11.31. The total mean score of the 6 patients who showed the beliefs was 12.83, and the score of the 28 who did not was 12.07.

The same analysis was done dividing the sample on the basis of presence or absence of any evidence of psychosis (see table 6). The 16 imipramine-treated patients who showed evidence of psychosis had a mean GIS score of 12.75±1.98, and the 5 who did not had a mean score of 12.80±2.17. The total mean score of these 21 patients was 12.76. The 9 placebo-treated patients who showed any evidence of psychosis had a mean score of 11.44±2.13, and the 4 who did not had a mean score of 11.0±1.41. The total mean score of these 13 patients was 11.23. The total mean score of the 25 patients who showed any evidence of psychosis was 12.28; for the 9 who did not it was 12.00.

In all of these analyses there was a main effect for drug (patients given imipramine improved more), no main effect for presence of delusions or other psychotic features, and no significant interaction, indicating that imipramine-treated patients with these psychopathological features improved as much as patients in

whom these features were absent. That is, depressed patients with pretreatment evidence of implausible belief, conviction of sinfulness, conviction of persecution, or belief in external control benefited from treatment with imipramine.

To further test whether the presence of delusions contraindicates the use of imipramine, the mean GIS score of imipramine-treated delusional patients was contrasted with that of imipramine-treated nondelusional patients by means of two-tailed t tests. This was done for each of the specific forms of psychopathology. In all cases the differences between means was nonsignificant. For presence or absence of implausible belief the t was .802, for conviction of sinfulness the t was .301, for conviction of persecution the t was .040, for implausible belief and/or belief in external control the t was .802, and for any evidence of psychosis the t was .060. In this sample, delusional depressive patients treated with imipramine did as well as nondelusional imipramine-treated patients.

Table 7 presents correlations between pretreatment scores on MSRPP items and GIS scores within the placebo and imipramine groups. Since a positive correlation indicates that high pretreatment pathology is associated with improvement, support of the hypothesis that imipramine treatment is contraindicated if delusions or other aspects of psychosis are present requires significant negative correlations. Six items were associated with the psychotic state. For imipramine-treated patients the 6 correlations tended to be either positive or essentially zero (see table 7).

The item "ideas of reference," which we believe is not pathognomonic of psychosis, had an insignificant negative correlation. This analysis is consistent with the analysis of variance and suggests that the presence of delusions does not contraindicate imipramine treatment in primary depressive illness.

Caution is required in generalizing from these data to other groups of deluded depressive patients. Delusions and hallucinations were not prominent features

of the symptoms of these patients. [illegible] these psychopathological features w[illegible] slight to mild. It is possible that in pa[illegible] sions and hallucinations are more p[illegible] mine might be ineffective, but no po[illegible] this effect has yet been presented.

Since most of the deluded depres[illegible] ported by Glassman and associates [illegible] poorly with imipramine were wom[illegible] exists that there might be some inter[illegible] lusions, and response to tricyclics. T[illegible] tions of pretreatment scores on items [illegible] chosis with GIS scores were examin[illegible] men and women within drug groups

There were no significant effects or even trends suggesting that sex affected treatment outcome. We also examined the ages and sex distribution of patients with delusions to determine if there was anything distinctive about each of these groups. For this analysis any evidence of implausible belief, conviction of persecution, conviction of sinfulness, or belief in external control qualified the patient as delusional. Seven men and 16 women met these criteria, and 5 men and 6 women did not. We examined the ages of these patients by treatment and presence or absence of these psychopathological features. There was a nonsignificant trend for patients receiving imipramine to be older, but there was no difference in age of patients with and without delusions (see table 8). The 14 delusional patients treated with imipramine had a mean age of 38.42±14.7, and the 7 nondelusional patients treated with imipramine had a mean age of 42.50±9.68. The total mean age of these 21 patients was 40.29. The 9 nondelusional patients given placebo had a mean age of 28.44±8.5, and the nondelusional patients given placebo had a mean age of 33±20.3. The total mean age of these 13 patients was 29.85. The total mean age of the 23 delusional patients was 34.09; for the 11 nondelusional patients it was 39.04. The two-tailed t test contrasting the means for the patients who received imipramine showed insignificant differences (t=.774).

COMMENT

The data presented in this paper do not support the hypothesis that imipramine is contraindicated in the treatment of primary depressive illness if delusions or other evidence of psychosis are present.

What possible explanations are there for the discrepancy between our data and those of Glassman and associates (1)? Their sample consisted of 12 women and 1 man; the average daily dose for the women was about 200 mg (3.5 mg of imipramine/kg of body weight). Hordern and associates (6), using a maximum dose of 200 mg/day, also found that the presence of delusions was associated with poor response to treatment with imipramine and amitriptyline.

In the present study all patients received 300 mg/day of imipramine. Previous studies contrasting tricyclic dosage regimens of 300 mg/day and 150 mg/day in depressed inpatients found the higher dosage regimen more effective on a variety of measures (7, 8). It is possible that doses of 200 mg/day are inadequate for deluded depressive patients. In addition, the patients of Glassman and associates received treatment for four weeks and the patients of Hordern and associates for four (an unspecified number of Hordern and associates' patients received treatment for six weeks), but patients in the present study received imipramine for five weeks before a final evaluation. Perhaps delusional patients require longer than four weeks on drug to improve.

Our clinical observations suggest that the manner in which some depressed patients treated with tricyclics improve implies the presence of a threshold that, once reached, is followed by marked clinical improvement. Before achieving the threshold there is little improvement. It is possible that delusional depressed patients are more severely ill, have a higher threshold, and, therefore, require more than 200 mg/day of tricyclics. Another, more remote possibility is that delusional depressive patients metabolize tricyclics in a manner necessitating higher doses of tricyclics to reach therapeutic levels.

Glassman and associates stated that delusional depressed patients should be regarded as diagnostically different from other severely depressed patients. However, other lines of evidence indicate that the presence of delusions does not differentiate two classes of patients with endogenous or major depressive disorder. Although not absolutely consistent, the trend in factor analytic studies has been to differentiate between endogenous and neurotic depressive patients rather than between psychotic and nonpsychotic primary depressive patients. Kiloh and associates (9), in a factor analytic study of 145 depressed patients in Australia, concluded that they had replicated the findings of an earlier study of 143 patients by Kiloh and Garside (10) in Newcastle. Their major finding was that endogenous and neurotic depressive patients can be differentiated and that neurotic depression is probably a dimensional disorder and heterogeneous. However, the endogenous form of the illness appears to be a condition with "a restricted range of clinical manifestations, consistent with an imputed genetic or biochemical basis" (9). Kiloh and associates did not find that the endogenous group split along a psychotic versus nonpsychotic dimension.

Guze and associates (11) divided a group of patients with primary affective disorder into those with and those without psychotic features depending on the presence or absence of delusions or hallucinations. They compared these patients on 40 demographic, family history, or parental variables and 75 symptom variables. No consistent meaningful differences were found between those with and those without psychotic features. We mention this sample of studies of the phenomenology of depressive illness to show that considerable data suggest that the presence of delusions does not indicate a separate class of depressive patients.

Our study fails to corroborate the claim that classifying affective illness into psychotic and nonpsychotic subtypes has differential treatment implications. Nosological formulations should be subject to periodic reevaluation in the light of new information. To clarify the existing ambiguities, studies of delusional depressive patients treated with different doses of imipramine for adequate periods while monitoring drug plasma levels should be done. Until these studies are carried out, asserting that delusional depressive patients form a special subgroup who require special treatment is premature.

Parent Assessment in Research on the Vulnerability of Children and Families to Mental Disorder

BY JOHN ROMANO, M.D., AND ROBERT H. GEERTSMA, PH.D.

The research methodology for a current study of the assessment of family factors as they relate to the development of psychopathology in high-risk children is described. Factor analysis of preliminary data from 83 families led to the construction of 6 rating scales on the emotional health of the patient, spouse, and child; the family; and the marriage; these should prove valuable in predicting the outcome of the index child and his family.

THE PROCEDURES and results described in this report are part of the project on Children and Families Vulnerable to Mental Disorder at the University of Rochester School of Medicine and Dentistry. This project, following a high-risk paradigm, uses a convergent, longitudinal design whereby a number of research teams prospectively study a population of families in which one parent has in the past been hospitalized for emotional illness and in which there is a male child of appropriate age. Collaboration of the research teams permits the investigation of a range of variables potentially relevant to the subsequent development of psychopathology in the index children.

METHOD

Sample

This analysis is based on 83 families in which one parent had previously been hospitalized for psychiatric illness and in which there was a male child of age 4, 7, or 10. All families were white and fell into social classes I to IV on the Hollingshead index (1). Families were not included in the analysis if the ill parent's hospitalization was for organic disorder, alcoholism, or drug abuse. The average age of the patients was 37.83 years. In 62 of the 83 families the ill parent was the mother. The diagnoses of the ill parent were distributed as follows: schizophrenia, 24%; affective psychosis, 10%; intermediate, 19%; and nonpsychotic, 47%.

Our investigative team engaged only the parents of the subject families and was generally concerned with documentation of interpersonal and personal (parent and caretaker) characteristics and the nature of caretaking patterns of behavior; characterization of parental-object relations; and analysis of the ill parent's illness, clinical course, and diagnosis.

Procedure

Two techniques were used to gather data—a semistructured interview and a form consistng of 36 adjective pairs (termed the object relations schemata). The data-gathering procedure was as follows: Both the patient and spouse were seen in a session lasting approximately 2 hours. One of the investigators (J.R.) conducted an interview in which the patient was first seen for about 50 minutes, the spouse for about 25 minutes, and then both of them for about 25 minutes. All of the interviews were videotaped. They focused on a number of issues, including the patient's past illness and current health, the effect of the illness on the patient's various social roles and on the family, child-rearing practices and experiences, the marital relationship, and the family interactions. The interviewer followed a preestablished format in that he systematically directed attention to a succession of topics. The interaction regarding these topics was as spontaneous and informal as the relationship with those being interviewed allowed.

While the patient was being interviewed, the spouse, using the object relations schemata, gave descriptions of the following objects: self, patient before illness, patient now, typical spouse, index child, typical child, and other children. Then, when the spouse was being interviewed, the patient gave descriptions that were similar, except that the "before illness" and "now" qualifiers applied to self.

Within several weeks after the data-gathering session the investigators watched a playback of the videotaped interviews. Notes were taken and subsequently used to prepare a narrative summary of the interview. The investigators separately scored each of 107 vari-

ables according to whether it was judged present (+), absent (−), or unratable (0); for a handful of variables (such as the probable type of emotional illness of a relative), choices were made among descriptive terms. The investigators' judgments were then compared and a consensus reached on variables not rated similarly. The overall agreement between the two investigators and one research assistant was approximately 83%. A diagnostic assessment of the patient at the time of the key admission was made at this time, as determined both from the interviews and available hospital records. There was also a diagnostic assessment of the current status of both patient and spouse. On the basis of this information a judgment was also made regarding the accuracy of the patient's previous hospital diagnosis, and in cases of disagreement, a rediagnosis was made. The current level of functioning of both patient and spouse and the patient's level of functioning during the illness were rated on the Global Assessment Scale of Endicott and associates (2). Finally, ratings were made on work and social competence, the degree of frankness in the interview, and the general orientation of each parent toward difficulties and problems.

The 107 variables, which cover those discussed in the literature (3–29) as well as those developed by the investigators, deal with the marital situation, caretaking, and parental roles, functions, and attitudes.[1] A number of variables were derived from the process described above. In addition to the separate variables rated from the interviews, a series of six desirability ratios were calculated from sets of items referring to the major aspects covered in the interviews (marital relationship, spouse, parenting, family, patient, and extrafamilial aspects). Each of the items in these subsets has been classified as desirable or undesirable according to our combined judgment as to whether the trait or behavior in question would be likely to support or undermine mental health. Variables for which such judgments could not be made with confidence were not included in the ratios. Each ratio score was then calculated by dividing the sum of variables rated in the desirable direction by the number of desirable and undesirable variables that were rated as either present or absent.

The object relations schemata comprise 36 bipolar descriptive items that permit a response on a 1–5 scale, with 3 falling midway between the two poles. The scale has 6 items in each of 6 categories: mood, thinking, task competence, activity-passivity, anger, and interpersonal relations. One item from each category refers specifically to the family. Test-retest reliability for the form was determined by retesting 7 randomly chosen subjects (5 patients and 2 spouses). The average interval between testing was 34 days. Average test-retest correlations (over 36 items) for descriptions of "patient before illness," "patient now," "spouse," and "index child" were .79, .84, .80, and .79, respectively. Prior to use in this study the ob schemata items were given weights acco classification by a lay population in ter bution of emotional illness. These weig used in the calculation of an emotiona each description. Descriptions made b wife with the object relations schemat tercorrelated to indicate the degree ceptions regarding themselves and the this point the data were in the form discrete variables. These variables wa related to outcome data on the index these become available and to variables vestigative teams assess on the same lation. [1] A sample list of the 107 variables is available from Dr. Romano on request.

sources are in agreement, although it should be recognized that the emotional illness indices reflect an indirect attribution, since they are secondary scores derived from descriptions of the spouse. The factor coefficient counterpart of this scale also loaded highly the spouse desirability ratio, which was not used for the scale because it requires many judgments from interview data.

Scale 2 represents the investigators' judgment of the patient's emotional health. It comprises variables referring both to the past and present. Because the judged intensity of past illness and pre-illness competence are substantially correlated with the current Global Assessment score, this scale can be viewed as referring to the patient's present condition.

Scale 3 consists of items that reflect the patient's self view, its emotional illness index, and its relation to views of the index child and the spouse's view of the patient.

Scale 4 presents the spouse's view of the patient's emotional health. The time focus can be taken as current, since the spouse's view of the patient before the illness appears to be highly related to his or her current view of the patient. This scale differs from the previous one in that the patient's view is not represented, whereas in scale 3 it is the major variable.

Scale 5 refers to the emotional health of the index child. It comprises variables based on the investigators' judgments and the parents' views so that, again, concordance of the three sources will produce the most extreme scores on this scale.

Scale 6 involves the family and the marital situation. The variables derive solely from the investigators' judgments. The 4 variables each reflect a plus (for present) or minus (for absent) rating given after reviewing the videotaped interviews of the family. If insufficient information or clarity is encountered, then the variable is rated zero and not subsequently counted for that family. By and large, the 4 variables on this scale were covered well by the interviews and could be rated for virtually all of the families in the sample. Lack of satisfaction in parenting was inferred from the way the mother described and talked about her activities as a parent. For this item to be scored as present the mother would have expressed essentially no enthusiasm or pleasure regarding her parenting role, and often she would elaborate on its burdens and difficulties.

Freedom of expression between the parents was rated as present when both parents indicated that their relationship included bringing up and discussing their problems and concerns. An absent rating was given when at least one parent indicated that such concerns were not generally aired or discussed.

Substantial conflict between the parents was judged present when they indicated that the expression of disagreement occurred or was a threat on a constant basis. The conflict had to be frequently expressed and had to be continuing so that it appeared to be a virtually permanent aspect of their relationship.

The presence or absence of a capacity to resolve child-rearing issues was inferred from parental descriptions of such issues and how they resolved them. Families that did not identify child-rearing issues of much concern to them were nevertheless rated as having the capacity to resolve such issues. Lack of such capacity was inferred from the presence of unresolved conflict that was an aggravation to at least one of the parents.

DISCUSSION

The data-gathering procedures of this study are pointed toward two types of subsequent analysis. In the first type, single variables (e.g., the effect of a shadow of an emotionally ill ancestor, the spouses assuming new roles in order to maintain the family after the patient's illness, the presence of support from members of the extended family) can be related to child outcome or to other variables. The variables rated from interview material were put in the present-absent format in order to avoid producing multidimensional response alternatives in one item (e.g., the parent's relationship is trusting, subject to frequent disruptions, or based on mutual dependence). Although the present-absent format requires clear ideas of where to draw the line between presence and absence, it was felt that it involves judgments that are simpler, closer to the relevant observational data, and that provide a more sound basis for subsequent statistical treatment, as in regression analysis.

The second type of analysis involves the results of the variable interrelationships represented by the scale scores. The 6 scales provide a multidimensional view of the structure of a family. Each dimension can be thought of as a strength or weakness. However, it should be noted that the dimensions preclude the coherent interpretation of the single variables that comprise them. The dimensions can be related to other variables singly or patternwise. For example, if the spouse's emotional health were a weakness for a family, the presence or absence of other weaknesses could be crucial to the outcome for the index child. Thus a pattern of weakness (low score) on scale 1 would have implications different from those of a pattern of weakness on scale 1 and scale 2 (patient's emotional health).

In summary, this report of work in progress gives data on a partial sample of 83 families studied. As of July 1978 we have completed the study of 148 families and have as our goal the study of 150 families. However, factorial structure has not changed significantly in the analyses of data from 40 families, 60 families, and 80 families. As is evident, we do not yet have any outcome data and therefore no definitive findings; this is essentially an exposition of methods. Factor analysis of our data led to the construction of 6 scales that we anticipate will be useful in predicting the outcome of the index child and his family.

Explaining the Increased Arrest Rate Among Mental Patients: The Changing Clientele of State Hospitals

BY HENRY J. STEADMAN, PH.D., JOSEPH J. COCOZZA, PH.D., AND MARY EVANS MELICK, PH.D.

The arrest rates of nearly 2,000 psychiatric patients released from psychiatric centers in 1968 and those of nearly 2,000 patients released in 1975 were compared with the arrest rates of a group of 5,000 patients studied 25 years earlier. In general, arrest rates among the two recent samples were considerably higher than general population rates, primarily because of the large proportion of patients previously arrested. Other characteristics related to subsequent arrest were age and admitting diagnosis. One additional finding was that the number of patients with prior arrests had increased markedly over the years.

VERY RARELY is the research literature as consistent in its findings as has been the case in the studies of arrest rates of former mental patients. Investigations reported before 1965 (1–4) noted that in every offense category former patients were arrested less often than were members of the general population. Since 1965 research studies (5–9) have found that in certain offense categories, varying from study to study, former patients were arrested more often than were members of the general population. Most distressing from the policy standpoint was that the offenses for which the patients tended to be most often arrested included assault, robbery, and rape.

All of these studies represent substantial work with unwieldy data that are most difficult to obtain. However, there are some limitations in each study that have restricted their policy applications. For example, the important work by Zitrin and colleagues (8) dealt with but one catchment area in one city (New York City), while another recent study (9) reported statewide data but these were from a highly rural state (Wyoming), thus limiting possible generalizations to more populous areas.

A further difficulty in interpreting these studies is that for the most part, their data relate to only one study group for one time period. This limitation is important, since these data have been interpreted as suggesting some unintended consequences that may have been precipitated by changes in mental health treatment orientations and practices. Unfortunately, the inferences about changing behavior patterns among former patients have rested on comparing one study's data with others, rather than having multiple time periods in the same location(s), which would directly address the changing arrest rates as alterations in the treatment systems were occurring.

The research reported here offers comprehensive data on a statewide sample of persons released from state psychiatric facilities at two different times. Moreover, since the setting of the research was New York State, we were able to compare our results with those obtained 30 years earlier by Brill and Malzberg (4). As a result, long-term trends in the characteristics and composition of patients in New York facilities could be measured. These add support to the recent data on higher arrest rates among persons released from state hospitals than for the general population. However, these data also provide an explanation of these changing rates based on the changing characteristics of persons provided services within the New York State system.

METHOD

Our two major interests in undertaking this research were to obtain comprehensive statewide data as current as possible while still having a reasonably long follow-up period and to obtain the same information on a group that would have been released before the effects of deinstitutionalization were manifest in the New York State system. To meet the first need we selected a sample of former patients who were 18 years of age or older and who were released from psychiatric centers between April 1, 1974, and March 31, 1975.[1] During this time there were approximately 35,000 patients released from state psychiatric centers. We selected every 18th release, which produced a 1975 study group of 1,938 subjects. By following these individuals through March 1976 we had on the average 19 months of risk.

Since the New York State program of reducing the number of inpatients began in earnest during the peri-

Dr. Steadman is Director and Dr. Melick is a Research Scientist, Special Projects Research Unit, New York State Department of Mental Hygiene, 44 Holland Ave., Albany, N.Y. 12229. Dr. Cocozza is Director, Bureau of Research and Program Evaluation, New York State Council on Children and Families, Albany, N.Y.

[1]This included patients who were discharged, escaped, or were put on leaves exceeding 5 days.

0002-953X/78/0007-0816$0.50 © 1978 American Psychiatric Association

od 1965–1966[2], we wished to draw our second study group as close to that period as possible. Because of restrictions in the Department of Mental Hygiene data processing systems, the oldest complete data set available was that for persons released between April 1, 1967, and March 31, 1968. Accordingly, we selected every 14th person released from psychiatric centers during this period to produce a second study group of 1,920 individuals.

Two types of data were gathered for both study groups. First, all hospitalization histories were obtained, together with a range of diagnostic and sociodemographic items stored in the Department of Mental Hygiene's data processing system. Second, the criminal records of those individuals who had prior and/or subsequent criminal records were obtained from the New York State Division of Criminal Justice Services. The division also provided the data from which the arrest rates of the general population were compiled.

FINDINGS

The first data we examined dealt with how many of our two groups of nearly 2,000 released mental patients were arrested after release and particularly how many for violent crimes. Of the 1,920 ex-patients in the 1968 study group, 131 (6.9%) were arrested during their first 19 months after release. Of the 1,938 subjects in the 1975 study group, 183 (9.4%) were arrested. Looking specifically at violent crimes (murder, manslaughter, and assault), 17 of the 1,920 ex-patients in the 1968 group (0.9%) were arrested for such offenses, compared with 33 of the 1,938 in the 1975 study group (1.7%). It is quite important to recognize how few of the persons released from state mental hospitals are arrested (6.9% and 9.4%, respectively, in the 1968 and 1975 groups) and even how many fewer are arrested for violent offenses (N=17 [0.9%] and N=33 [1.7%], respectively). Too often the infrequency of such events is forgotten in the heat of the particularly bizarre or violent behavior of a former patient, which is given considerable media coverage.

However, such absolute numbers are not sufficient to make the equally important comparisons with the arrest rates of the general population, members of which are also seldom arrested. To examine such questions, these absolute figures must be converted to base rates of the number of persons in the various groups who were arrested for every thousand people in each group. The data in table 1 make such a conversion for our two study groups and for the general population of New York for the same years.

As is evident, our data show statewide patterns fairly similar to what Zitrin and colleagues (8) found locally in one catchment area in New York [illegible] all other post-1965 studies in this area [illegible] strated. The major difference between our [illegible] others' is that in both our study groups [illegible] tients were not only arrested more often [illegible] was the New York State general population [illegible] also were arrested more often for every [illegible] gory but one. The only exception to this [illegible] slightly lower rates for sex crimes in the [illegible] For total arrests, the 1968 group was arrested [illegible] as often than the general population [illegible] group was arrested 3.0 times as often [illegible] vidual offense categories, excluding the [illegible] for sex crimes, the former patients were [illegible] 2.1 times as often for potentially violent [illegible] the 1968 group to 7.0 times as often [illegible] crimes in the 1975 group, compared with [illegible] population.

Having found these substantial differences [illegible] ex-mental patients and the general population [illegible] tinued to analyze our data to determine [illegible] tain characteristics of the released patients [illegible] lated to their arrests after release. Our findings [illegible] strated that the overall rates in table 1 [illegible] misleading.

TABLE 1
Annual Arrest Rates per Thousand for 1968 and 1975 [illegible] and the General New York State Population*

Item	Arrest Rate per [illegible]		
	1968 Sample		
	General Population	Patient Sample	[illegible]
Total subsequent arrests	27.53	73.50	
Violent crimes (murder, manslaughter, assault)	2.29	5.58	
Potentially violent crimes (robbery, arson)	1.85	3.94	
Sex crimes (rape, sodomy, sexual abuse)	0.42	0.33	
Drug crimes	2.32	14.77	
Crimes against property (burglary, larceny, forgery)	4.50	23.95	
Minor crimes (vagrancy, public intoxication)	10.19	20.34	

*Per 1,000 persons 18 years of age and older.

Factors Related to Subsequent Arrest

In examining a wide variety of variables [illegible] that there were only three factors that [illegible] tically significant contributions in explaining [illegible] the former patients were subsequently arrested [illegible] der of importance, they were total prior [illegible]

[2]The decrease is apparent in the number of resident patients at the end of the following fiscal years: 1960—93,855; 1965—89,216; 1970—66,529; and 1975—34,032.

TABLE 2
Relationship Between Prior and Subsequent Arrests for 1975 Patient Samples During 19-Month Follow-Up*

Number of Total Subsequent Arrests	Total Prior Arrests: 0 (N=1,428)		1 (N=187)		2 (N=97)		3 or more (N=226)	
	N	%	N	%	N	%	N	%
0	1,387	97.1	158	84.5	66	68.0	144	63.7
1	32	2.2	23	12.3	26	26.8	45	19.9
2 or more	9	0.6	6	3.2	5	5.2	37	16.4

and admitting diagnosis.[3] Table 2 displays the relationship between prior and subsequent arrests for the 1975 study group. As we will do below in our discussion of the relationship between diagnosis and arrest, in the interests of clarity of presentation we have omitted the 1968 data since they are very similar both in the size and directions of the relationships found in the 1975 data. It is more instructive to examine this table than to simply view the .351 zero-order correlation between the two factors (.371 for the 1968 group). From table 2 it is apparent that the strength of the relationship comes from the steadily increasing probability that those with more prior arrests will have more subsequent arrests. Whereas 97.1% of the 1975 group without prior arrests were not arrested, with one arrest this percentage decreased to 84.5%, to 68.0% with two prior arrests, and with three or more prior arrests to 63.7%. Thus the factor of a prior arrest record is systematically and strongly related to subsequent arrest.

As expected, age was also related to subsequent arrest. The median age of those subsequently arrested in the 1968 sample was 42, compared with 51 for those not arrested. The average age of the 1975 former patients who were subsequently arrested was 35, compared with 45 for those not arrested. The zero-order correlation between age and subsequent arrests was .112 for the 1968 ex-patients and .142 for the 1975 group.

The only other factor that was significantly related to subsequent arrest was admitting diagnosis. Table 3 presents this relationship for the 1975 group. What is most apparent is the significant difference in the percent arrested among those given a diagnosis of substance abuse and personality disorder compared with all other diagnostic groupings. Whereas no more than 8% of the subjects in any other major diagnostic category were subsequently arrested, 18% of those with either alcohol or drug diagnoses and 28% of those with personality disorders were arrested. One of the factors apparently causing this relationship was that persons particularly prone to subsequent arrest were younger individuals diagnosed as substance abusers. This interactive effect ultimately indicated that the more important factor statistically was age. Nevertheless, the role of alcohol and drugs in re-arrest rates found in earlier works (9) appears to receive some further support from our data.

[3]The multiple R for these variables for the 1968 group was .400 and, for the 1975 group, .372.

TABLE 3
Relationship Between Subsequent Arrest and Admitting Diagnosis for the 1975 Released Patients*

Admitting Diagnosis	Total Subsequent Arrests: 0		1		2 or more	
	N	%	N	%	N	%
Organic brain syndrome (N=179)	171	95.5	4	2.2	4	2.2

Number of Prior Arrests

After completing our preliminary analyses showing a history of prior arrests to be the most important factor associated with subsequent re-arrest, we recalculated the rates of subsequent arrest for the two study groups, separating the released patients with one prior arrest and those with two or more prior arrests from the patients with no prior police record. These data, reported in table 4, are the most important for properly understanding the arrest rates of former patients.

In fact, the arrest rate in every offense category but one (property offense) for those patients released from New York State facilities in 1975 with no prior police records is lower than that of the general population. Overall, 22.1 per 1,000 former patients with no prior arrests were subsequently arrested, compared with the general population rate of 32.5 per 1,000. Again, the ex-patient with no prior police record was subsequently arrested for violent crimes at a rate of approximately 2.2 per 1,000, compared with 3.6 per 1,000 for the general population. Those patients returning to the community who had no police record before admission had substantially lower rates of arrest than did the general population.

However, when we examine those released patients with 1 arrest before hospitalization, the total rate jumps to 138 per 1,000 for all arrests and to 3.4 per 1,000 for violent crimes. Even more dramatic are the rate increases for persons with multiple prior arrests. Their rate of re-arrest for all offenses leaps to 413.5 per 1,000 and to 60.5 per 1,000 for violent offenses. Thus the arrest rates for all former patients are considerably higher than those of the general population primarily due to those individuals who have been arrested before they entered state facilities. Those with multiple prior arrests are disproportionate contributors. It is only in the multiple prior arrest group (2.9% of all 1,938 sampled patients) that the rate of arrest for vio-

TABLE 5
Comparison of Findings by Brill and Malzberg and Findings from 1968 and 1975 Released Male Patients

Item	Brill and Malzberg 1947 Sample	1968 Sample	1975 Sample
Number of male former patients	5,354	1,075	1,088
Length of follow-up	5.6 years	19 months	19 months
Prior arrest before current hospitalization	803 (15.0%)	343 (31.9%)	435 (40.0%)
Those with prior arrest subsequently arrested	273 (34.0%)	107 (31.2%)	128 (29.4%)
Those without prior arrest subsequently arrested	92 (2.0%)	15 (2.0%)	26 (4.0%)

lent offenses exceeds that of the general population, and quite dramatically so.

While these data are insightful in their own right, they become even more instructive when compared with the earlier work done in New York by Brill and Malzberg, who studied only male released patients (4). In looking at the statewide arrest rates of men released from New York State facilities in 1947, these authors found former male patients arrested less often than the general population for all categories of offenses. While this finding is often cited, what is equally important but usually overlooked is that the rates of subsequent arrest among those ex-patients with prior records were substantially different from those of patients with no arrests prior to hospitalization. Table 5 compares Brill and Malzberg's data in this area with those of the men in our two study groups.

Most striking in the data in table 5 are the substantial increases in the percentage of the state hospital male patients who had a police record prior to their admission. In Brill and Malzberg's study only 15% of the male patients had prior police records whereas our 1968 sample included 32% with prior records and the 1975 group had 40%. This substantial increase is important in interpreting patient arrest rates in that, as table 5 also shows, the percentage of those with prior arrests and those without prior arrests w
sequently arrested has remained practic
over the 30-year-period these data compr

DISCUSSION

A number of suggestions have been
plain the increasing arrest rate among
patients. Dominant among these sugge
that recent community treatment ideolo
grams have put more persons who are
into the community. Further, this ex
pointed to the overreactions to such pro
states that have "dumped" persons no
dependent living into high crime areas
developments may have contributed to
found over a 30-year period in New
more parsimonious explanation, which
cally supported from the data reported h
composition of state hospital populatio
in ways directly related to increasing the
postrelease arrest. Rather than focusing
of mental health systems, our data le

more at the systems' inputs, which have changed substantially.

In any group of individuals, those who have previously been arrested are much more apt to be arrested than those without prior arrest. This, of course, is not to say that one could accurately designate those who will be arrested by this single factor without inaccurately selecting many who would not be arrested. However, if one were to gather a group of men, of whom 40% had previously been arrested, from the general population, it is quite likely that the arrest rates found among the 1975 former patient group would be duplicated or exceeded. It may be surprising, but there are no data to accurately indicate what percentage of the general population has ever been arrested. While police agencies at both the state and federal level can provide data on the rates of arrest, they are unable to offer current figures on how many people have ever been arrested. Brill and Malzberg reported an estimate from a correctional source that placed this figure in the mid-1950s at about 5% of the general population. This estimate contrasts sharply with the 15% of Brill and Malzberg's sample of men who had previous arrests and even more so with the 32% and 40% in our two study groups previously arrested. These discrepancies in themselves point out why the general population and ex-patient rates vary so widely and why arrest rates of former patients have increased so substantially over the past 30 years.

Just why the number of patients with prior arrests has changed goes beyond the data we have gathered. The exchanges in responsibilities that may have occurred between the criminal justice and mental health systems over 30 years would require analyses beyond those possible here. Similarly, one could only guess at the ways in which the recent state of mental health litigation has contributed to these changes in patient characteristics. Whatever the causes, it is certain that there has been some shift in practice, if not in policy, so that persons who formerly would have been caught in the "revolving cell door" are now bouncing back and forth between state hospitals and jails as solutions are sought in mental health treatment for what are usually nuisance behaviors or property offenses. It is instructive to note how accurate for our data are the observations of Drs. Brill and Malzberg, who wrote nearly 25 years earlier:

> Arrests in the ex-mental hospital patients were very largely concentrated in a relatively small, rather well-demarcated group of persons with previous criminal records, and their anti-social behavior was clearly correlated with well-known factors which operate in the general population and was not correlated with the factors of mental illness except in a negative way. Available standards indicate that the rate of subsequent arrest among ex-mental patients with a record of criminal arrest prior to hospitalization was, if anything, lower than rates of rearrest in persons with similar records who had not been in a mental hospital.
>
> The conclusion drawn from this survey is that attack of mental illness with hospitalization does not tend to leave an inclination toward criminal activity greater than that which existed prior to the illness and that it does not produce such a tendency if it did not previously exist. . . . (4, pp. 12–13)

Many changes in mental health treatments and ideology may have occurred since 1947, but the fundamental explanation for the arrest rates of former mental patients posited by Brill and Malzberg remains true today.

Animal-Human Correlates of Narcotic Dependence: A Brief Review

BY BARRY STIMMEL, M.D., AND STANLEY D. GLICK, PH.D., M.D.

Knowledge of opiate action in laboratory animals can be of great value in developing a rational clinical approach to the treatment of narcotic dependence. Physiological alterations experimentally produced by narcotics have been confirmed in human subjects, and classical laboratory effects of conditioning and operant behavior also have clinical counterparts. Realization of animal-human correlates of narcotic dependence allows a better understanding of the strengths and weaknesses of existing therapeutic modalities.

IN ATTEMPTING to provide a better understanding of the pathophysiology of human disorders, scientists are constantly searching for animal models of human diseases which they can study and more clearly define. Despite our similarities to mammals and even primates, such attempts in most instances are frustrating. One area that has been fruitful relates to the study of pharmacological and physiological effects of narcotic drugs in producing dependence, tolerance, and withdrawal.

Although the exact mechanisms underlying these phenomena are still unknown, recent exciting advances have been made with respect to the location of opiate receptors (1). Opiate receptor activity is found in the amygdala, periaqueductal gray matter of the midbrain, hypothalamus, caudate nucleus, and the medial thalamic area. Other areas of the thalamus and the cerebral cortex have also been shown to exhibit opiate binding to various degrees. In addition, brain extracts from naïve animals have been found to contain morphinelike substances which not only bind to the opiate receptor but also have opiatelike effects on isolated tissues. Such findings will undoubtedly stimulate further investigations to clarify the mechanism of analgesia, euphoria, tolerance, and dependence readily observed with narcotic agents. A great deal of information has already been elicited concerning the behavioral effects of narcotic agents on the organism. These observations can be of help in clinically unders addicts' compulsive craving for narc great difficulty in maintaining abstinenc

Unfortunately, this information has n disseminated and is known more by scie engaged in research in drug dependence professionals clinically active in the fie sulted in the proliferation of theories ab of narcotics on psychosocial behavio ance of advocates of a particular ther to the exclusion of all others.

The purpose of this paper is to review of animal behavior that are affected by n dence and, with the use of this knowled the advantages and disadvantages of c ties of therapy. It should be emphasize view is directed toward the health profe field of drug dependence. For this reas presented an exhaustive bibliography o detail experiments conducted at the lab It is also important to realize that focusi cological and physiological effects of dr way negates or minimizes the psych cioeconomic forces that undoubtedly p in initiating narcotic dependence and in preventing maintenance of the abstin addicts.

DEPENDENCE

Wikler (2) has used a conditioning th dependence to formulate an operatio framework for relating experimental a pects of narcotic dependence. Drug dep fined as "habitual, nonmedically indica ing and drug using behavior which is co maintenance upon pharmacological an not necessarily upon social reinforcem concept, one can measure the overall s dependence by its resistance to extinc degree of physical dependence being re verity of withdrawal symptoms induced ministration of the drug is discontinued

Narcotics readily produce dependenc animals. Although the addition of morp ing water results in a bitter-tasting liqu dence has developed rats choose morp and self-administer the drug, even in th

sive stimuli (3, 4). Although it is frequently assumed that repeated administration of a narcotic for a prolonged period is a prerequisite of dependence, this is not the case. In naïve chronic spinal dogs, phenomena indicative of hind limb abstinence can be precipitated by nalorphine administration 1 hour after a single dose of morphine (5). Similarly, in man, unequivocal physical abstinence phenomena indicating dependence can be precipitated by nalorphine injection after administration of analgesic doses of morphine, methadone, or heroin four times a day for as few as 2–3 days (6).

Physical dependence need not be present for reinforcement to be obtained from opiate administration (7). Environmental factors or expected responses from injection of a specific agent may provide reinforcement, even when there is no opiate in the solution administered. Stolerman and Kumar (4) have demonstrated the presence of conditioned reinforcement in rats used to ingesting bitter morphine solutions. These animals, when offered a bitter-tasting quinine solution, consumed more than naïve rats because of the prior association of bitterness with morphine reinforcement. Similarly, clinical experience has shown that individuals accustomed to injecting heroin cut with quinine may experience a "high" when only quinine is injected and, indeed, may have been consuming such a poor quality of heroin that they may not show signs of physical dependence when challenged with a narcotic antagonist (8).

There is evidence that the acquisition of a drug "habit" may be facilitated in the presence of anxiety or stress. Rats will learn to self-administer amobarbital when a state of anxiety is provoked by the use of random electric foot shocks (9). Clinically, in addition to the fact that anxiety facilitates narcotic use, the cultural phenomena surrounding the injection of narcotics introduce the user into a defined social group, albeit a deviant one, which also serves as a positive reinforcement.

TOLERANCE

Narcotics also have the ability to produce tolerance on repeated injection. The development of tolerance also affects the self-administration of the drug, necessitating higher doses for a pleasurable effect to persist. It is not surprising that the response of laboratory animals does not differ from that of humans in this respect. Daily intravenous self-administration of morphine by rhesus monkeys will increase gradually over a course of 4–6 weeks and then stabilize, presumably indicating that tolerance has developed (10).

CHRONIC EFFECTS OF OPIATE USE

Physiological alterations produced by narcotics have been shown to persist long after administration of a narcotic has been discontinued and in the absence of obvious withdrawal symptoms. Altered responses of laboratory animals to painful stimuli have been found up to 12 months after production of morphine dependence (2, 11). Loss of tolerance to morphine analgesia in rats was incomplete up to 12 months after morphine withdrawal, with EEC responses to morphine challenge remaining different from those of naïve control animals (11). Clinically, alteration of the respiratory center of man to atmospheres containing carbon dioxide has likewise been shown to persist for prolonged periods of time following discontinuation of narcotic agents (12).

ABSTINENCE AND WITHDRAWAL

The physiological disturbance of the abstinent state can be well demonstrated in the laboratory animal. This is not only related to the actual physiologic and pharmacologic effects of ceasing narcotic administration but also can be the result of conditioning. A conditioned abstinence syndrome can be produced by the use of paired nonaversive stimuli given during the production of abstinence when the animal is dependent. Thus narcotic-free rats will undergo withdrawal when placed in an environment that has been associated with production of the abstinent state during previous physiological withdrawal (13). Monkeys that have been narcotic-free for up to 4 months will experience withdrawal in response to a visual or auditory stimulus previously associated with a withdrawal-inducing nalorphine injection (14). Wikler (6, 15) has been able to provide evidence for the conditioning ability of nalorphine-precipitated abstinence in man by producing abstinence when saline injections were substituted for nalorphine. This conditioning effect has long been known "on the street," where addicts become uncomfortable and actually develop signs and symptoms of withdrawal when, in the narcotic-free state, they enter an environment where they had previously experienced withdrawal.

It is also important to realize that symptoms and signs of withdrawal, although most prominent in the immediate postnarcotic dependent period, have also been found to persist for considerable periods of time. Narcotic-dependent rats exhibit signs of abstinence that may persist for 5 months after withdrawal of morphine (16). Similarly, monkeys have been shown to exhibit abstinence phenomena for up to 120 days after discontinuation of narcotics (17). Such animals, if previously trained to self-administer opiates, will relapse promptly after morphine withdrawal. Rats will consume a significantly larger volume of an opioid solution than control animals for up to 1 year postaddiction (16). This may be associated with increases in metabolic rate, norepinephrine excretion, and locomotor activity (18). Whether such a relapse results from permanent physiological alterations in the organism induced by initial morphine dependence, a protracted physiological abstinence state, a conditioning process,

or a combination of all three has not been clearly determined. Nonetheless, such effects do persist, have been documented in man for up to 30 weeks post-withdrawal, and must be considered in the therapy of heroin dependence (19).

THERAPEUTIC GOALS

After consideration of the knowledge gained from animal experiments, it becomes important to outline desirable objectives when dealing with the narcotic addict. It is not sufficient to merely withdraw the addict from narcotics either abruptly or with slow detoxification. One must address 1) reasons leading to narcotic use, 2) actual physiologic changes produced by chronic narcotic use as well as acute and chronic abstinence, 3) existing stimuli associated with narcotic reinforcement, 4) operant behavior surrounding self-administration, 5) existing stimuli associated with withdrawal, and finally 6) means of altering long-term behavior so as to maximize the possibility of an individual remaining narcotic-free. However, it should be emphasized that, if the physiologic changes produced by chronic narcotic use in an individual are sufficiently profound, maintenance of abstinence may not be realistic. In such cases therapeutic goals would be directed toward the first five factors, with alteration in long-term behavior implying the ability to lead a socially productive and personally fulfilling life without abstinence being a primary goal.

RESIDENCY HOUSES

Most persons respond to pain or anxiety in one of several ways: fear, rage, or isolation. Manifestations of the fear are flight or denial; of rage, acting out; and of isolation, internal withdrawal or "encapsulation." Heroin use facilitates the "encapsulation" response by allowing the addict to build a shell around himself that must be removed before the therapeutic process can begin. Residency houses attempt to explore the individual's feelings and get through the "impenetrable" barrier by group processes centralized in encounters, either pro- or introspective. Existing stimuli associated with drug reinforcement and withdrawal are removed through the encounter mechanism as well as by forced compliance with the "house rules." Deviation is not tolerated, infractions are dealt with, often severely (e.g., aversive stimuli). The operant behavior surrounding narcotic administration is attacked through incarceration (albeit voluntary) within the community setting, associated with close observation by not only staff but also other residents. Verbal therapy through encounter groups as well as individual contact serves to facilitate extinction of previously conditioned responses. Gradually the support offered by the staff as well as the punishment they deliver creates a role model through which the individual is able to alter behavior on a prolonged basis in the abs[illegible] sive stimuli. Education and training, ini[illegible] by assigning jobs of increasing difficul[illegible] house setting, can be expanded to profe[illegible] tional training and/or formal education.

Such therapy would be most success[illegible] persons whose physiologic dependence [illegible] has not been firmly established or w[illegible] traordinarily high degree of motivation [illegible] narcotic use. The presence of actual p[illegible] dence is easily identifiable in the abse[illegible] testing with a narcotic antagonist, even [illegible] of prolonged narcotic use exists. Blacidy [illegible] over 40% of applicants to a methadone [illegible] program with a positive history of he[illegible] oin in their urine showed no withdraw[illegible] following naloxone administration. Alth[illegible] psychologically dependent on the drug, [illegible] have not developed a true physical de[illegible] cause they have used an extremely poo[illegible] oin or have used the drug intermittently[illegible] hand, individuals who are not able to tol[illegible] environment or who have a severe de[illegible] narcotic agent may find great difficulty [illegible] their increasing anxiety in such settings. [illegible] plain the high "split" rate seen in re[illegible] houses, as well as the use of alcohol or t[illegible] lieu of narcotics. When the closed env[illegible] primary inhibiting factor, benefit may be [illegible] drug-free programs on an ambulatory ba[illegible] experience has indicated that ambulat[illegible] usually does little to remove the existin[illegible] ciated with drug use or the operant beha[illegible] ing self-administration. For this reason [illegible] are rarely effective in enabling an indi[illegible] tain the abstinent state.

NARCOTIC ANTAGONISTS

The use of narcotic antagonists (cyclo[illegible] one, or naltrexone) in heroin-dependen[illegible] have been detoxified from narcotics will[illegible] the euphoric effect of heroin should it be [illegible] Such agents, however, have the potent[illegible] inforcing the stimulus associated wit[illegible] administered too early in the abstinen[illegible] tion, experimentally, antagonists at lo[illegible] been found to have a reinforcing effect [illegible] opiate administration. Only at higher [illegible] tinction occur (20). The initial occurrenc[illegible] morphine-seeking activity may be therap[illegible] eficial if a daily blocking dose of an ant[illegible] ministered, as it will facilitate extinction[illegible] ty when the reinforcing effect of eupho[illegible] tained. Once this behavior has been e[illegible] may be possible to discontinue use of th[illegible] tagonist. If relapse is purely psychologi[illegible] repeated administration of an antagonis[illegible] in a marked diminution of heroin use and [illegible]

relapse. If, however, persistent physiological and biochemical alterations induced by narcotic drugs are prominent, once abstinent such a person might find great difficulty in maintaining the drug-free state, and administration of narcotic antagonists might intensify the physiological effects of chronic abstinence. In this regard, it is also important to realize that most narcotic antagonists also have an agonistic effect and are mild analgesics with the capacity to alter mood and cause some degree of euphoria and dependence. Although euphorigenic effects without sedation, associated with increased activity, have been considered to enhance rehabilitation efforts (21), the danger of dependence upon such antagonists is real and must be considered quite carefully (22). Cyclazocine and nalorphine can produce physical dependence similar to that seen with morphine. Discontinuation of these agents also results in a comparable abstinence syndrome, somewhat slower in onset and associated with drug-craving or drug-seeking behavior (23). Naloxone is an exception in that it has only antagonist effects. Unfortunately, the short duration of action of naloxone, associated with its relatively low potency and its high cost, has prevented its use as a long-term pharmacologic agent (24, 25). Naltrexone, the cyclopropylmethyl analogue of naloxone, is also reported to have minimal agonistic properties and is currently under study (26, 27). Further work is necessary before these agents can be recommended as standard alternative therapeutic modalities for heroin dependence.

The use of narcotic antagonists in combination with behavioral therapy has been advocated by Wikler (15). With this technique the addict who has been detoxified and maintained on an antagonist in an inpatient setting is presented with controlled conditioned stimuli to elicit the conditioned response, which is subsequently eliminated through supervised self-injection of the narcotic in doses insufficient to overcome the antagonist blockade. It is anticipated that subsequent to the repetition of this process, previously experienced stimuli will cease to evoke a conditioned response. Once the patient is discharged, therapy with the narcotic antagonist might be continued for at least a year to maintain extinction should a relapse to previous conditioned stimuli occur in the ambulatory setting.

METHADONE MAINTENANCE

The substitution therapy most often used in this country is methadone maintenance. The reasons for using methadone rather than other narcotic agents relate to its long duration of action, its effectiveness when administered orally, and its inability to cause euphoria or somnolence when given in appropriate doses to tolerant individuals. Thompson (28) has demonstrated experimentally the ability of methadone to suppress self-administration of morphine, thereby diminishing the probability of seeking further drug reinforcement. Methadone extinguishes the operant behavior associated with withdrawal. When administered in appropriate dosages so as to slowly raise the tolerance threshold, it will also extinguish morphine-seeking behavior by preventing euphoria following injection of street heroin. This last point is worthy of emphasis, since methadone, like any other narcotic, can cause euphoria and/or narcosis when administered to a nontolerant individual or in a dose that exceeds the individual's tolerance. Administration of methadone, therefore, allows the addict to remain comfortable, free of both the psychological anxieties and physiological realities associated with withdrawal. The protection against the "high" is similar to that achieved with narcotic antagonists, although, unlike the person on antagonists, there is no discomfort related to abstinence. Methadone also eliminates operant behavior surrounding self-administration, but only of the narcotic agents. If anxiety still exists, the individual will seek other mood-altering drugs. This explains the not infrequent association of polydrug abuse in methadone programs, most prominently drugs in the alcohol-barbiturate-tranquilizer group.

Methadone and other pharmacological modalities, however, do not address either the factors that lead to heroin injection or the alteration of behavior to effect long-term changes. For this reason pharmaceutical agents should be only one component in the rehabilitative effort. Such programs should be staffed with multidisciplinary professional personnel to provide the ex-addict with the psychological and vocational support necessary to allow the fullest realization of his or her potential. It should be emphasized that not everyone is a candidate for long-term methadone maintenance. For those whose addiction is of short duration or is intermittent rather than constant, another therapeutic modality may be of value.

CONCLUSIONS

It is quite important, regardless of what modality is recommended, to realize that many factors related to persistent heroin use are not imagined but are based on solid experimental evidence. It is extremely difficult for a heroin addict to give up the "habit." This difficulty is not necessarily associated with a weak personality; it is related to the existence and persistence of pharmacological, physiological, and conditioned behavioral changes. Each person must be individually evaluated to assess the prominence of these factors, with subsequent recommendations to appropriate modalities. When this is done, the chances of successful rehabilitation are maximized to the benefit of both the individual and the community.

Causes for the Premature Interruption of Psychotherapy by Private Practice Patients

BY PERITZ LEVINSON, M.D., LEITH MCMURRAY, M.D., PAUL PODELL, M.D., AND HOWARD WEINER, M.D.

Thirty patients who discontinued private psychotherapy prematurely were evaluated. Factors stemming from the dynamic interaction between the patient and the treatment process were the most common reasons for dropping out, followed by chronic character traits such as impulsivity and masochism. It is hoped that this assessment of variables in the premature termination of therapy will serve to alert the therapist to the probability that treatment will be aborted, suggest which mechanisms will cause interruption, and enable the therapist to use preventive measures sooner.

THERE IS AN established bibliography dealing with outcome in psychotherapy, predictability, and reasons for patients dropping out. However, the studies in this area are generally limited to the measurement of factors that are not difficult to define, objectify, and quantify. They include demographic variables such as age, social class, and intelligence, which can be readily and objectively measured, in addition to such factors as the patient's ego strength, diagnosis, and motivation and the therapist's empathy, which are also not very difficult to assess. What is lacking in this area of research is an effort to elucidate psychodynamic factors in the therapeutic process that lead to premature interruption and their interaction with other variables. Only with this more subtle information will the therapist be able to deal effectively with premature termination, both preventively as well as when the crisis develops. Without these data the therapist is equipped only with information as to which patients are likely to drop out of treatment and which are not.

This area has not been researched adequately because of the difficulty in identifying psychodynamic elements on a cause-and-effect basis from a myriad of alternatives. This requires a degree of inference that makes the resulting judgments vulnerable. Another recognized difficulty is defining the psychodynamic variable itself (such as transference) so that several experienced judges will share a commonality of meaning.

Drs. Levinson and Podell are Assistant Clinical Professors, Mount Sinai School of Medicine, New York, N.Y. Drs. McMurray and Weiner are Associate Psychiatrists, Lenox Hill Hospital, New York, N.Y. Address reprint requests to Dr. Levinson, 120 East 89th St., New York, N.Y. 10028.

The authors wish to thank Dr. Walter Reichman, Baruch College, who served as research consultant.

LITERATURE REVIEW

Brandt (1) reviewed 25 studies of adult patients who were in individual long-term psychotherapy at outpatient clinics and terminated clearly without the therapist's concurrence. "Acceptors" of treatment had a high level of education, annual income, and motivation and were more likely than the "rejectors" to have been referred by physicians, courts, and themselves rather than by social agencies. McNair and associates (2) found that remaining in therapy was related to the degree of interest the therapist expressed in the type of problem presented by the patient. Borghi (3) observed that termination of therapy was a result of incongruence between expectations of the patient and the therapist. Shapiro (4) studied 24 child and adolescent clinic patients and found that premature termination may be a behavioral reaction to the negative feelings of therapists and that families seem to evoke less negative countertransference than do individual patients. Weber and associates (5) observed that unfavorable outcome was related to severity of pathology, such defense mechanisms as denial and projection, fragile personality organization, a proclivity for strongly dependent transference relationships, and a tendency to elicit negative countertransference.

In a comprehensive review Luborsky and associates (6) examined 166 "valid" quantitative studies of factors that influenced the outcome of individual psychotherapy for selected adult patients from 1946 through 1969. Among patient factors, adequacy of general personality functioning, motivation, expectation of change, payment of fee, intelligence, anxiety, and affect all correlated positively with outcome and nontermination, as did self-awareness, interest in human relations, achievement, and likability. Ethnocentrism, defensiveness, and somatic concern were negatively related to outcome. Among therapist factors, level of experience, skill, and interest as well as empathy, warmth, and genuineness were positively correlated, as was similarity between the therapist and patient in social class, interests, values, and orientation to interpersonal relations. Seeman (7) noted that terminators

 0002-953X/78/0007-0826$0.50 © 1978 American Psychiatric Association

tended to drop out of therapy with the advent of transference elements similar to those that were prominent and troublesome in adolescence and that led to avoidance instead of intrafamily confrontation and resolution.

Weiner (8) attributed psychotherapeutic impasse primarily to incongruence of the therapist's and patient's goals, inappropriateness of the therapy prescribed, lack of rapport, and an antitherapeutic alliance. Kohut (9) discussed analysands who quit suddenly because of a narcissistic insult or threatened deprivation. Cooperman (10) emphasized the need of the patient dropout to defeat the therapist by thwarting the treatment or breaking it off. Rosenfeld (11) underscored the interruption of therapy based on a negative therapeutic reaction. Loewald (12) observed that the more intractable negative therapeutic reaction was refractory to interpretation because of guilt and the need for punishment. Stone (13) identified the causes for premature interruption in the therapy of wealthy individuals as extreme narcissism and manipulation by the patient and envy, contempt, and corruptibility through overcharging by the therapist.

METHOD

We undertook to study a series of 30 prematurely terminating private outpatients from the standpoint of psychodynamic as well as fixed variables. Our sample was different from that in most studies of patient dropouts, which have dealt with clinic patients from a lower socioeconomic group.

We met on alternate weeks. We were similar in that we ranged in age from 38 to 46, had been in practice for 12 to 17 years, were university trained, and spent most of our workweek in private practice in Manhattan doing primarily psychoanalytically oriented psychotherapy of a supportive-expressive type. One case was presented at each meeting, with an emphasis on data concerning the premature interruption of therapy. The time at each session was divided approximately as follows: 1 hour for a general presentation of the case and 30 minutes for a discussion of factors specifically related to the interruption of therapy. Each of us, using an inventory of causative factors, then rated the case independently in order to assess rater reliability. This was followed by another 30 minutes for general discussion and elucidation of the data. Finally, there was a composite rating of factors based on the four individual ratings.

There was no preselection of patients in that each of us presented all of the cases qualifying as premature interruption that occurred in our practice from a point 2 years before the beginning of the project. The criteria for premature termination of therapy were as follows: 1) the patient had weekly sessions for a minimum of 3 months and 12 treatment hours, 2) the ending was relatively abrupt, 3) termination was unilateral and without the therapist's concurrence, and 4) the main goals remained unaccomplished. Each of us ha[d] [to] cases. All patients were treated contin[uously] schedule of 1 or 2 sessions per week. Th[e] duration of treatment was 9 months and [the] ber of sessions 41. Most of the patients [had] out of therapy within 6 months of the ti[me] were presented, and 67% of the subjects [were] ment during the project; hence we were [alert] of premature termination and the fact [that] Cases were not presented until 4 month[s] nation to ensure that they were true ter[mi]nations not just "recesses."

In constructing the inventory of reason[s] leaving therapy, we attempted to be over[in]clusive listed variables that could prove valid as [well] that we thought would not. Although a [5]-point was used to rate the degree to which a ca[use] was involved in the termination of thera[py], the number of cases falling into each point [was] sary to regard the variable as existent [or] rather than as quantitatively assessed. [Cate]gory definitions were continuously discusse[d] would retain a reasonably uniform und[er]standing the terms and concepts.[1] In addition to [the] ry items, several other factors were d[e]emed consensus to lead to premature terminat[ion]. transference and iatrogenicity. The last category, "reality factors" (40%), included interpersonal causes such as family or spouse interference, reality factors such as moving away and loss of money, and therapist absence when it was not iatrogenically based. In regard to this last factor, all absences were within reasonable expectable limits in respect to timing and duration.

In studying table 2, it is important to keep in mind that premature interruption of therapy appeared to be a multidetermined action with a mean of 3 causative factors per case in this group of patients. Transference factors, fear of loss of defenses, fear of dependence, and fear of aggression or sexuality, in that order, were the most common individual causes for dropping out. Transference was listed as one cause of the interruption in 60% of all cases. The most frequent nontreatment-reactive factor was countertransference, which appeared to be a cause for dropping out in one-third of the cases. Other causes listed in at least 20% of the cases were interference from family or spouse, masochism, negativism, fear of success (or need to fail), and complications related to therapist absences. Interestingly, reality factors, which are often offered to rationalize leaving therapy, caused premature interruption in only 1 case.

Table 3 presents diagnostic data on the 30 patients. More than half were diagnosed as having a personality disorder, 30% as borderline personality, and 17% as schizophrenic. None of the 30 dropouts was diagnosed as having a neurosis.

We also analyzed the epidemiological and treatment characteristics of the total dropout group, excluding categories that did not show significance or trends, and the breakdown by causes for leaving therapy.[2] The following can be noted:

Transference, which was the most common cause for leaving therapy, tended to occur among those who were married, Catholic, had more frequent therapy

[2]A table presenting these data is available from Dr. Levinson on request.

sessions, were not schizophrenic, and who approached 50% of their treatment goals. (Goals in all cases included symptom relief as well as restructuring.) Transference was particularly related to leaving therapy when the diagnosis was personality disorder.

More men than women left therapy because of fear of loss of defenses or fear of dependence. However, men who left for fear of loss of defenses were more likely to be married, whereas those who left for fear of dependence tended to be divorced.

There were fewer Jews and more Protestants and Catholics among those who left for fear of dependence. Those who left for this reason tended to be diagnosed as borderline; none were diagnosed as schizophrenic. They also tended to achieve 50% of their goals.

Of the 11 subjects who left for fear of aggression or sexuality, 9 also left because of transference. Therefore, a separate analysis was not done for the category of fear of aggression. However, chi-square analysis indicated that women, Jews, and patients with less ego strength were less likely to drop out for this reason.

Those who left due to intrinsic factors tended to be slightly older and married or divorced, very few were single. More of these patients were diagnosed as borderline and schizophrenic than those who did not leave due to intrinsic factors.

Of those who left because of therapist factors, more tended to be single and few divorced. More were schizophrenic, compared to the total group, and they tended to leave therapy gradually; few left semi-abruptly. These patients tended to approach 50% goal achievement.

The fourth category, reality factors, was not included in the analysis because it played a relatively small role in termination and did not show any particular trends.

Those subjects with greater ego strength were more likely to have a personality disorder than a more severe illness and to have more goal achievement. Greater ego strength was associated with dropping out due to treatment-reactive causes, mainly fear of loss of defenses and fear of aggression or sexuality. This is logical in view of the "stronger" patient having fewer chronic, intrinsic personality traits, inciting less negative therapist response, and constructing a life featuring less destructive family influence and less social and economic instability and impermanence.

Another finding was that the reasons for leaving therapy which involved therapist-patient interaction (transference, dependence, therapist factors) led to achievement of more of the therapy goals than did other reasons for terminating. It appears that involvement with the therapist, even in an aborted therapy, is productive to the well-being of the patient. Perhaps therapists ought not to consider patient termination as much of a failure when the cause of termination is related to their interaction with the patient.

The following vignette concerns termination of therapy due to therapist-patient interaction.

Sudden Infant Death Syndrome: Impact on Families and a Direction for Change

BY STANLEY E. WEINSTEIN, M.S.W.

Until recently, there were no standardized approaches to the diagnosis of sudden infant death syndrome (SIDS), the leading cause of death in the age group of one week to one year in the United States. This has led to confusion among professionals and hardships for parents and families. The Sudden Infant Death Syndrome Act of 1974 provided funding for the dissemination of information, counseling, and education. The author reviews the scope of the SIDS problem, the ways in which it affects families, and mechanisms by which community resources can be mobilized to assist families.

SUDDEN INFANT DEATH SYNDROME (SIDS), commonly referred to as "crib death," is the leading cause of death in infants between the ages of 1 week and 1 year in the United States. SIDS is the unexpected death of an apparently healthy infant for which thorough postmortem examination fails to find an adequate cause. The syndrome occurs more often in the colder seasons and usually when the infant is sleeping. Accurate statistics are not available for the incidence of SIDS in the United States because, until recently, autopsies were performed in only 50% of the cases and many communities did not list SIDS as an approved category on death certificates. However, it is estimated that between 8,000 and 10,000 infants die each year of SIDS. Diagnostic procedures and official causes of death vary from community to community.

The ambiguous nature of SIDS makes many physicians, clinical investigators, and pathologists uncomfortable. Theories of causation have included enlarged thymus gland, allergy to cow's milk, suffocation from bedding, infection, and immature heart. Some important areas of current research include studies relating to prolonged sleep apnea (1), chronic oxygen deficiency (2), and enzyme abnormalities: [illegible] have yielded promising results. Other [illegible] of the SIDS pattern tend to include [illegible] mothers under 20, preceding colds, [illegible] cidence at 2–4 months of age (3). Upp[illegible] infections have been associated with SI[illegible] infants who die of SIDS have suffered fre[illegible] tions. Only recently have investigators l[illegible] at SIDS as the end result of an interac[illegible] factors, which may not be the same in a[illegible]

Bergman (4) reported that 14% of the [illegible] sample said they had not been told wh[illegible] died, 50% felt that they were not give[illegible] explanation of the cause of death, and 8[illegible] the death was caused by a disease tha[illegible] from the cause listed on the death certif[illegible] of the 74 primary counties reported in th[illegible] considered to have an organized appro[illegible] with problems related to SIDS.

Bergman attempted to assess how co[illegible] knowledged the problem of SIDS and the[illegible] offered. One variable examined was "[illegible] sources." Bergman found that only one [illegible] association out of 48 had an organized [illegible] local health departments were involved [illegible] grams, and no state health department h[illegible] gram. The community resources Berg[illegible] were physicians (usually pediatricians) [illegible] edgeable public health nurses, occasiona[illegible] gist, and, at best, a chapter of a parent [illegible] the International Guild for Infant Surv[illegible] the National SIDS Foundation. In ma[illegible] were no community resources for th[illegible] SIDS. The services offered by the few [illegible] sources that did exist were the provis[illegible] tion and/or counseling. Bergman concl[illegible] lies which did not have a private phys[illegible] apt to receive the worst care and attent[illegible] poorer families in our society have a h[illegible] of SIDS and the least access to inform[illegible] seling available through community res[illegible]

Information about SIDS is necessary f[illegible] involved and for the general public. The[illegible] to have all of the available information [illegible] order to understand the disease as much [illegible] This may have been less of a concern in [illegible] other diseases (e.g., tuberculosis, sm[illegible] monia) were claiming the lives of more c[illegible] however, SIDS is the leading cause of in[illegible]

accounting for almost one-third of infant deaths after 1 week of age (3).

THE FAMILY'S RESPONSE TO SIDS

Families experiencing a SIDS death generally face multiple problems. The situation may have been worse in the past, but it is still bad today. The parents are often young and may be experiencing the death of a relative for the first time. It is often the first major stress on their marriage. They had waited nine months for the birth and were just sampling the joys and adjustment of parenthood when their infant child died. They ask the logical question—"Why did my baby die?" They look to their physician for answers, but he does not have them. They want to make sense out of nonsense and put the pieces together in a way that will enable them to see a cause and effect. If there is no autopsy, they will wonder about the cause even if it is listed as SIDS, and they will have no knowledge about possible genetic defects. The autopsy is a procedure that says to parents, "We have looked and found no other known cause of death." The cause of death may be reported as pneumonia, particularly if there is no autopsy or if a coroner does not recognize SIDS as a cause of death. This may imply neglect on the part of the parents, and even if others do not say this, the parents certainly consider it themselves. If the parents have a lifestyle that is at variance with that of middle-class America, they may even be accused of child abuse. A number of parents have been charged with child abuse and imprisoned, even while their infant was being buried. It is often not realized that for the age range of one week to one year many more deaths are caused by SIDS than by child abuse. An autopsy can rule out abuse. Parents and families look for a reason—a germ, a defect, or some logical cause. The atmosphere of not knowing the cause generally leads parents to dwell on their own doubts or doubts suggested by others and to blame themselves for doing—or failing to do—something that led to the death. "If I had stayed home, I would have heard him." "If the window wasn't open." "If I had taken him to the doctor sooner." "If I hadn't left him with a babysitter." These statements may reflect the parent's feeling that "If I were a better parent" or "If I hadn't sinned," the child would be alive.

A common denominator of SIDS parents is guilt. The guilt, the grief, and the lack of knowledge together constitute major emotional stress for the parents both as individuals and as a couple. Guilt can exacerbate previous psychiatric conditions and marital problems. The grief and mourning are doubly hard because the parents had no preparation—the infants were viewed as thriving and healthy, not sickly. If the family has other children, what do they tell them? If the sibling shared a bedroom, do the parents wonder if the other child somehow caused the death? Could normal sibling jealousy or "death wishes" confuse the sibling to the point of believing he or she killed the infant (magical thinking)? What about future pregnancies? Could this happen again? How soon should the couple try to have another child and what can they do to prevent a recurrence of this tragedy? There are many concerns and many questions, but where do these families turn? The Bergman study (4) noted that physicians and parent groups were the two main community resources.

In the past the marital pair, the family, and the kinship group were considered the best support systems. The family is still the major support, although in our complex society the family is unable to handle all problems. As our industrialized society moved away from total reliance on the extended family to cope with family stress, formal community care-giving agencies were developed to provide these resources. The death of an infant, with the grief and mourning that follows, generates a crisis for all individuals within a family. It is important to note that this crisis may temporarily induce behavior that appears similar to mental illness, but "a state of crisis is not an illness" (6) and should not be seen as such. "Crises . . . represent mental health turning points or way stations. The balance may come down on one side or the other; there is the opportunity for a healthier development and the danger of a move toward pathology" (7). Some families grow closer as a result of dealing with crisis and others develop major problems. Studies show that before a state of illness, physical or mental, there is often a crisis that upsets a person's or family's previous level of functioning (8). Other studies (9–11) show the later effects of a child's death on siblings and parents. Thus a severe problem caused by the sudden infant death syndrome can affect the health of all family members. Community resources not only serve to help at a time of stress but can also serve a preventive function.

THE SUDDEN INFANT DEATH SYNDROME ACT OF 1974

Parent groups were the first community resource organized to deal with problems related to SIDS. The first such organizations were developed during the early 1960s by SIDS parents to provide information to newly bereaved families, educate the general public, support research, and facilitate change in the way communities respond to the problem. They also began to counsel SIDS families on a number of issues, including their guilt, their other children, the children they may have in the future, and their grief reactions. They attempted to provide these services because there was no other organized community resource available, and they knew that the circumstances surrounding this death were unique, generating many unique problems and requiring a unique kind of counseling. However, community response was slow to change and more families needed service than these groups could accommodate. These groups, along with some interested professionals, took their concerns

about SIDS problems to the United States Congress for hearings in 1972 and 1973. The Bergman study (4) was presented as evidence, and the result of the hearings was the passage of the Sudden Infant Death Syndrome Act of 1974. The act directed the Department of Health, Education, and Welfare to fund a number of SIDS projects around the country through the Bureau of Community Health Services, Maternal and Child Health Services.

These SIDS projects are specialized community resources set up to provide counseling services to families who have lost a child through SIDS, to educate the general public, and to mobilize and educate special groups of people who come in contact with these families. These special groups are defined as police, physicians, funeral directors, emergency room personnel, ambulance drivers, clergymen, and pathologists (12). These are not just special groups; they are also professional caregivers. Thus it is incorrect to say that there were no resources in the communities Bergman studied; rather, there were community resources that were not being used as support systems for families who experienced SIDS. Viewing community resources this way, one can also consider a number of others such as the medical examiner, the family service agency, the school counselor, the psychiatric clinic, and parent groups. All of these community resources are important, and for a given family in a community one cannot predict which resources will be received in the easiest or most meaningful way or will offer the best help. Assuming all community resources were good and available to all families, factors such as the culture of the family and history of the family's association with the particular resource, plus the age and sex and socioeconomic level of the family members, might determine which resources would be utilized.

COMMUNITY RESOURCES

How does one identify, educate, and support community resource systems? One starts by evaluating a particular community to see what resources exist at both state and local levels and in the public and private sectors. First, it is necessary to determine whether services should be built into existing delivery systems or whether new systems should be developed. To elicit effectively the support of other community agencies and professional caretaking groups, it is necessary to understand their view of their role and the way in which they perceive SIDS and the families of SIDS victims. One way to do this is to appoint professional agency representatives as consultants to the SIDS educational and counseling program. For example, in order to change the type of service SIDS families receive in hospital emergency rooms, it would be necessary to develop an educational program tailored to this goal. However, one must first understand the current service and the views of the emergency room staff toward change. An advisory group of representatives from various community hospitals, large and [illegible] and private, would be of great assistance.

Another question that needs answering is who should do the educating. Should the [illegible] DHEW-funded projects do the educating or someone else? Community resources should be examined so that one can understand how [illegible] training or inservice educational programs. The DHEW project staff can do the educating themselves or work toward using existing educational programs. Often it is better to take the latter course through consultation with and education of existing teachers instead of providing outside information is more likely to be accepted if presented by someone from within the system than a perceived outsider with special skills. For example, an educational program run by police academy instructors with SIDS project staff as consultants is better received than a program provided by the SIDS project staff.

ASSISTING A SIDS FAMILY THROUGH THE USE OF COMMUNITY RESOURCES

Listed below are guidelines that are [illegible] portant in dealing with a sudden infant death. The relevance of each of these to particular agencies or individuals will depend to some extent on the specific case and their relationship to the family.

1. Life-saving measures should be performed by those first on the scene (i.e., ambulance attendants or police officers), if for no other reason than to assure the family that every effort was made to save the infant. Parents often look to ambulance attendants or personnel as the people most likely to be able to save their infant. A parent's feeling of guilt may be increased when the professionals do not try.

2. There should be provisions for [illegible] ents to the hospital and for seeing that their infants are looked after. Once at the hospital, parents should be afforded privacy and access to a telephone in order to contact relatives, a clergyman, or their physician, and an emergency room staff member should be assigned as a link between the staff and the parents while efforts are made to revive the infant. Before informed of the death, parents should be given an opportunity to see the infant again should they desire, and the infant should be clothed or covered appropriately.

3. The need for an autopsy within [illegible] be emphasized and results of the autopsy should be shared immediately with the family. The autopsy examination in all communities should be performed so that there is agreement among pathologists on the use of the discrete category of SIDS.

4. Those dealing with the family at these stages should maintain a nonjudgmental attitude, doing their utmost to avoid implications of culpability in the infant's death. Often, [illegible]

must be investigated by the medical examiner's office or the police. In such cases, only factual data should be collected. Possible concerns about suspected child abuse can be clarified by the autopsy. If SIDS is suspected as a cause of death, the family should be referred to available literature and provided with suggestions for counseling.

5. Those who might be sought by the family for counseling, e.g., physicians, clergymen, public health nurses, psychiatric clinics, health departments, community agencies, or funeral directors, should acquaint themselves with the problems faced by such families and should be aware of other community resources to which they can refer the family.

6. Above all, those dealing with death should be concerned with the needs of the living—the family members whose distress could result in prolonged emotional problems, concerns about having additional children, or difficulties with further pregnancies if they are not given appropriate support in their time of crisis (12, 13). These families, including extended family members and siblings, often require specific guidance in such areas as making funeral arrangements. They may also need help with future crisis points, including the anniversary of the birth and death of the infant, the birth of other children, and Mother's Day and Father's Day.

Those assisting SIDS families should also be aware of the informal network of friends, relatives, employees, etc., who make up a large and often significant source of support for family members (14). These informal resources are usually available to families in crisis, and often their existence minimizes the need for long-term support from more formal community resources.

Caplan (7) has stated that "we can never aim at removing all problems from the world . . . we can, however, assist community leaders to arrange facilities so that people who are facing inevitable stress situations may be helped to solve their problems in a healthy way." The families experiencing the stress of sudden infant death syndrome deserve the care, concern, and assistance available through resources in their community.

Father-Son Incest: Underreported Psychiatric Problem?

BY KATHARINE N. DIXON, M.D., L. EUGENE ARNOLD, M.D., AND KENNETH CALESTRO, M.

Six families are described in which 10 sons were involved incestuously with a natural father (N=4) or step-father (N=2). Father-son incest as a part of the spectrum of child abuse appears to be a more frequent clinical entity than was thought previously.

THERE HAS BEEN increasing public and professional awareness over the past decade of parental sexual exploitation of children as a form of child abuse. The psychiatric literature contains a number of studies describing clinical features and suggesting dynamic formulations associated with heterosexual parent-child incest (1), but there is a significant lack of discussion dealing with homosexual parent-child incest. It is unclear whether this conspicuous dearth of information reflects a very low incidence of homosexual incest, as suggested by some authors (2–4); a tendency to label this behavior pattern as simply homosexual rather than incestuous, as Cory (5) has implied; clinicians' failure to recognize the problem; or a combination of all three factors.

During a period of 4 years, cases involving six families with homosexual incest have come to our attention. We were not looking for incest but, rather, were impressed by the accidental finding of such a large number of homosexual incest cases in our population in view of the lack of attention the phenomenon has received to date in the literature. All of our cases involved father-son incest, and we are aware of no cases of mother-daughter or mother-son incest in the same clinical population.

CASE REPORTS

Case 1

Larry A, 5½ years old and the oldest of two children, was seen in the clinic over a period of 2 years for problems of hyperactivity, aggressive behavior, encopresis, and poor peer relationships. His IQ scores were in the b[illegible] tal retardation range. His mother, a dependen[illegible] woman, had been married and divorced twice [illegible] from each marriage.

After Larry had been in treatment for a yea[illegible] reported spontaneously that his natural father [illegible] put his ding-dong where I go pooh-pooh [illegible] The natural father was known to have been [illegible] sive when Larry was an infant. He reportedly [illegible] blanket and threw him into the crib from a [illegible] episode of sexual molestation probably occu[illegible] father was caring for Larry during Mrs. A's h[illegible] Larry was 5 years old at the time, and Mrs. [illegible] obtained a divorce from the father. The fathe[illegible] of Larry appeared to be more upsetting and di[illegible] mother than to Larry.

Case 2

Doug B, a 6-year-old boy who was the olde[illegible] dren, was hospitalized for evaluation of possi[illegible] by the father. Since Doug had begun talkin[illegible] complained to his mother that the father wa[illegible] genitals and putting his mouth on Doug's [illegible] these incidents were witnessed by the mothe[illegible] and bite marks were sometimes found around [illegible] The mother reported finding bruises on the ch[illegible] claimed resulted from his father striking him. [illegible] in a double bed with his father since infa[illegible] mother slept in a single bed in the same roo[illegible] younger children was molested by the fathe[illegible]

In a clinical interview, Doug was observed [illegible] overactive and became particularly agitate[illegible] tioned about his father. His remarks about th[illegible] ed "He stinks. He's drunk. He hits me. I'd [illegible] and burn down his bar." It was reported that [illegible] feces in a can and often urinated on the living r[illegible]

Mrs. B filed for divorce because of Mr. B's [illegible] ual abuse of the child. Mrs. B had a history [illegible] and psychiatric hospitalization, and custody [illegible] awarded to the father during the divorce proc[illegible] was not seen for follow-up or treatment.

Case 3

Steve C, 11 years old and the oldest of fou[illegible] brought to the outpatient clinic by his mo[illegible] learned that her husband, Steve's stepfathe[illegible] gaging Steve in sexual activity over the pre[illegible] The three daughters, natural children of this [illegible] been sexually abused. Steve's natural fathe[illegible] when Steve was 18 months old, but Steve was [illegible] Mr. C was his stepfather.

Mr. C, an alcoholic, was described as "ove[illegible]" by wife. She said he showed pornographic films [illegible] ions and locked the children out of the hous[illegible]

intercourse with the babysitter. Mrs. C displayed some hysterical features and claimed that her husband often had intercourse with her while she was asleep. Steve had apparently watched at least one of these episodes on his stepfather's invitation.

During the two-year involvement with his stepfather, Steve had a series of accidents which included two near-drownings, several falls, and being struck by an automobile.

Mrs. C divorced her husband, but Steve did not continue his outpatient contacts with his therapist. He was next seen 3½ years later when he was admitted to the Adolescent Inpatient Service for refusing to attend school, conflict with his mother, defiance, running away, drug abuse, and at least one drug overdose. He was an anxious, insecure, and impulsive adolescent who was concerned about his own sexuality. His intelligence was in the low normal range. In a therapeutic program, Steve made positive gains with his many self-defeating, self-destructive, and maladaptive behaviors and was discharged home to his mother.

Case 4

Joe D, age 13, was the oldest of three children. He was referred for psychiatric treatment by the county children's services agency after discovery of his bisexual incestuous activity in his home. Police raided the family's trailer after receiving information suggesting that the patient's stepfather was moonshining and selling alcohol to minors. During the course of their investigation, they also discovered approximately 300 pornographic photographs depicting various sexual activities between Joe and his 11-year-old sister and his stepfather, and between the stepfather and Joe's sister. Subsequent physical examination of Joe's 3-year-old brother supported the children's later reports that he also had been repeatedly sodomized by Mr. D, who was this child's biological father.

The psychiatric evaluator found Joe to be a plump, immature, effeminate-appearing adolescent. He refused to discuss the home situation other than to say, "My father is rotten." His intelligence was above average (full scale IQ of 118 on the Wechsler Intelligence Scale for Children), and there was no evidence of a psychotic disorder or of significant depression. Results of psychological testing were essentially within normal limits, although there were indications that Joe was passive, submissive, cynical, and confused concerning issues of sexuality, rejecting the stereotypic masculine role. He also expressed overt hostility toward the father figure. Neither of Joe's siblings was referred for psychiatric evaluation. Short-term psychiatric admission was requested by and for Joe as a form of asylum from the notoriety this case had received in his small rural home community. Although the intrafamilial sexual activity had existed for at least 1 year, the patient was performing satisfactorily at school and no other problems were reported at the time of referral.

The patient's mother, who was in her mid-30s at the time of his admission, had suffered a stroke when Joe was 2 years old. Following this episode she showed significant personality and behavioral changes that interfered with her ability to care for herself and her young children. She was deserted by her first husband soon after her stroke and married Mr. D when Joe was 10 years old. She was pregnant with her youngest child at that time. She apparently was not a direct participant in the family's sexual activities with the children, although she was present during the photographing. The mother stated that she was fearful of physical violence from her husband and claimed she could do nothing to stop him. The stepfather, who was in his mid-40s, was described as violently explosive and had a record of convictions for manslaughter, bootlegging, and sale of pornography.

Mrs. D went into hiding for 3 months after the police discovered the family activities, later stating that she feared reprisals from her husband owing to her preliminary testimony. She subsequently refused to testify against Mr. D, as did the children. Their refusal, as well as the fact that the photographs could not be used because they had been seized without a warrant, led to the assault charges against Mr. D being dropped. He was convicted of selling liquor to minors and served a short sentence.

A 2-year follow-up revealed that Mr. and Mrs. D had separated and Mrs. D and her children had moved out of state. Joe's adjustment was reported as good, with no difficulties at school, home, or on his part-time job.

Case 5

David E, a 15-year-old boy, was originally seen for a psychiatric consultation on the surgical service, where he had been admitted for evaluation of headaches and neck pain. David had complained of various somatic problems for the previous 6 months, including chest and abdominal pain. For 3 months he had become progressively more withdrawn and depressed, with anorexia, insomnia, and self-mutilation. David and his mother led the consultant to believe that the depressive symptoms were temporally related to a change from special classes to a regular classroom, where he was unable to keep up with the work.

After several nonproductive sessions in which David remained withdrawn and uncommunicative, emergency psychiatric hospitalization was required for a crisis in which David was cutting his arms and legs and threatening harm to himself and his father. After his admission, with urging from his mother, David divulged the family secret that his father had been sexually abusing all six children in the family (two daughters, ages 13 and 14, and four sons, ages 8, 10, 12, and 15) over a period of 10 years. The youngest son had been treated for rectal incontinence at a pediatric clinic, but apparently no inquiries had been made to determine the cause. The mother claimed she had overt knowledge of this activity for only 1½ years but had taken no action to protect the children. The father's relationship with the children included a clear sadistic component, and he often beat them in combination with his sexual abuse. When the family noted the father to be in a "bad mood," the oldest daughter or son would "offer" herself or himself to protect the younger children.

All of the children in this family had significant school problems and several of them, including David, were in classes for the educable mentally retarded. David's achievement scores as a 9th grade student were on second, third and fourth grade levels. David's IQ, reported as 64 on a Stanford Binet at age 11, rose to 88 after his hospital admission and sharing the family secret.

The mother was able to follow through with divorce proceedings but then allowed the father to return home to live. None of the family appeared in court to testify against the father on the incest charges, which were consequently dropped.

At follow-up 3 years after the initial contact, the father had moved out of the home and remarried, though he continued to live across the street from the family home. He remained involved with the children at least to the extent of intruding into the relationships between his daughters and their boyfriends. All of the children continued to have school and

emotional difficulties. The oldest daughter sought counseling, and David called his former therapist once asking for advice about his impotence with his girlfriend. He was, however, unwilling to become involved in further treatment. None of the children received further help because the mother did not want to "open up old wounds."

Case 6

Richard F, 16 years old, was the second of five children. He requested psychiatric admission for "nervousness," which he attributed to several years of sexual abuse by his father. He had not attended school for the previous year and had spent his time "sitting around the house." In addition to running away frequently, he used alcohol and marijuana excessively. A history of "accidents" since age 12 included a gunshot wound in the chest deliberately inflicted by a friend, burns from "lying on a register," a fall from a roof, and assorted hand and knee injuries. There were numerous other clinical indicators of anxiety and depression.

Richard's parents had an 18-year history of marital and sexual problems. Mrs. F was aware when she married Mr. F that he had been involved homosexually with his brother and her brother. She suspected his sexual involvement with Richard from the time Richard was 10 but never attempted to confirm her suspicions. On a number of occasions she awakened in the middle of the night and heard Mr. F in the son's room, but accepted at face value her husband's explanation that he was "just checking Richard." Father and son were involved homosexually almost nightly from the time Richard was 14, and only when Richard openly confronted his mother 2 years later did she take any action. The charges she filed with the police against her husband were almost immediately withdrawn "at the children's insistence," she claimed.

Mr. F, a fifth grade drop-out, had been unemployed for several years, disabled due to "nerves." He drank excessively and was physically abusive with all his children. He whipped one son with a belt for 20 minutes "because he wouldn't cry." He openly admitted the sexual relationship with his son, blaming it on the poor sexual relationship with his wife.

Mrs. F, an anxious, suspicious, hostile woman, stated that she was unable to leave her husband because she could not support the family herself. Her history indicated that she was able to do little other than complain about the many terrible things her husband had done. She appeared overwhelmed by family and marital conflict but was unable to use the support of a social agency to help her cope with her problems.

Although there were four sons and a daughter in the family, only Richard had been singled out for his father's advances. An older son had a history of impulsiveness, excessive alcohol use, and drug abuse. At age 19, he had been married and on welfare for 2 years. One year after the initial contact, a younger son was seen on an emergency basis in the psychiatry outpatient clinic because of threatened violence and increasing conflict with the father. Fearful of being forced into a homosexual relationship, as Richard had been at his age, he was having some difficulty sleeping and was feeling homicidal toward his father, whom he accused of doing "awful" things.

No significant changes occurred within the family as a result of the family's and sons' psychiatric contacts, and after Richard's second admission he was discharged directly to the Job Corps.

DISCUSSION AND CONCLUSIONS

It is generally agreed that father-daugh... involves more than two people and is an e... intrafamilial conflict and pathology. Som... ingredients conducive to father-daughter ... poor marital relationship, an overburd... adequate mother who has usually abdicat... role, and a father with a poor sexual ad...

Although firm generalizable conclus... factors associated with father-son ince... drawn from these six families, there ar... table patterns that warrant attention ... identified patients were the oldest of mul... However, younger siblings were also ... fathers generally had histories of alcoh... athy, or both. Four fathers were known ... and physically abusive with the children ... had a history of poor judgment and imp... None was known to be homosexually ... other than immediate family or close rel...

There seemed to be a high degree of ... the part of the mothers. In several c... known about the sexual activity, overtly ... for several years before community reco... problem or direct confrontation by the ... them to take some action that could ... vention. They often appeared overwhe... able to protect their children, even with ... some cases.

In father-daughter incest, the daughte... anger and resentment toward both paren... as perpetrator and the mother as nonpro... cases, the sons expressed intense nega... even homicidal wishes, toward the fathe... of the families did the son describe the ... nonprotector.

Homicidal and/or suicidal ideation ... four of the six identified patients. Three ... fied patients had a history of self-dest... some form, ranging from suicidal gestur... tilation to reckless use of drug combina... tiple "accidents." None of the 10 be... families was psychotic.

All six families were white, even tho... population includes a substantial prop... races (approximately 20% black). How... skew could occur by chance in a series ... of the families were in the lower three ... socioeconomic classes, and five of the ... were urban. The clinic serves primarily ... and the socioeconomic distribution of ... normal.

There did not seem to be a consistent ... ther-daughter sexual abuse in the prese... sexual incest. Five families had both m... children. In two of these families, both ... male children were sexually used by the ... three families the sons were the only ta... ther's sexual abuse.

Following public disclosure of the family secret, at least one family member was extruded from the family system, usually the father or son. In one case, the mother was essentially extruded when custody was awarded to the father in a contested divorce. In one case, the disclosure was made after the father had left the home.

In general, there seem to be more parallels between father-son and father-daughter incest than between father-son and mother-son incest. This would suggest that the sex of the parent is a more important variable than the sex of the child.

The clinical experience from which these cases were drawn consisted of approximately 1500 cases of male child and adolescent patients. Thus, these cases represent 0.4% of our male child psychiatry patients. Since our patient population is not atypical in other regards for a child psychiatry service, it seems reasonable to expect that the frequency of father-son incest in the overall child psychiatric clinic population is higher than has been assumed.

BRIEF COMMUNICATIONS

Effect of Haloperidol and Apomorphine Treatment on Dopamine Receptors in Pituitary and Striatum

BY WILLIAM C. FRIEND, M.SC., GREGORY M. BROWN, M.D., PH.D., GEORGE JAWAHIR, TYRONE LEE, PH.D., AND PHILIP SEEMAN, M.D., PH.D.

Prompted by an interest in the similarity of brain and tuberoinfundibular systems, the authors studied butaclamol-specific neuroleptic and apomorphine binding in pituitary and striatum after chronic haloperidol and acute apomorphine treatment. Striatal binding increases but pituitary binding decreases in haloperidol-treated rats. Pituitary binding changes rapidly in response to apomorphine exposure and striatal binding does not. These findings suggest that factors influencing binding differ in these two tissues.

CONSIDERABLE INDIRECT EVIDENCE indicates that neuroleptic drugs act by blocking dopamine receptors. For example, the molecular structure of chlorpromazine, in its preferred conformation, can be partially superimposed on the dopamine molecule and so might act by fitting into the dopamine receptor (1). Neuroleptics produce the parkinsonian symptoms of rigidity, tremor, and akinesia (2), which can be partially reversed by L-dopa treatment (3, 4). Neuroleptics block the effects of apomorphine (5) and amphetamine (6), accelerate dopamine turnover (6, 7), increase the firing rate of dopamine neurons (8), and increase homovanillic acid accumulation (9). Further, t[illegible] a[illegible] fective inhibitors of dopamine-sensitive a[illegible] clase (10, 11). The recent finding that [illegible] compete with dopamine for stereospecific [illegible] in membrane fractions in vitro and that th[illegible] compete can be correlated with their cli[illegible] to control schizophrenia provides direct [illegible] the dopamine receptor-blocking action of [illegible] (12–14).

During the past decade, it has become [illegible] dopamine plays a major inhibitory role in [illegible] amic control of prolactin secretion. Dop[illegible] act by stimulating the release of some as[illegible] tified hypothalamic prolactin-inhibiting f[illegible] then travels to the pituitary via the porta[illegible] ternatively, dopamine itself could act di[illegible] pituitary as a prolactin-inhibiting factor. F[illegible] cal and physiological evidence exist to sup[illegible] ond hypothesis. Tuberoinfundibular do[illegible] rons terminate in the median eminence be[illegible] tal vessels, and although these neurons ar[illegible] nerve terminals which possibly contain [illegible] regulatory factors (15), the basal hypoth[illegible] tains few, if any, dopamine receptors tha[illegible] volved in triggering the release of a non[illegible] lactin-inhibiting factor. However, pituitary [illegible] contain dopamine receptors (16). Ph[illegible] dopamine directly inhibits prolactin secret[illegible] tuitary glands incubated in vitro (17, 18): [illegible] extracts also inhibit prolactin secretion [illegible] their inhibitory effect can be totally acco[illegible] the presence of dopamine and norepine[illegible] extract (19). Finally, neuroleptic treatm[illegible] an increased prolactin secretion, proba[illegible] blockade of pituitary dopamine receptors [illegible] hibition of prolactin secretion by dopa[illegible] does not occur if haloperidol is added to[illegible] (20).

The tuberoinfundibular-pituitary dopam[illegible] syste[illegible]

might serve as a convenient model of brain dopamine systems such as the nigrostriatal and mesolimbic systems. For example, the measurement of pituitary hormones, which can now be done with relative ease, might provide an index of the extent of central dopamine blockade produced by neuroleptics. As a test of whether the tuberoinfundibular-pituitary system could be used in this way, it seemed appropriate to compare the response of dopamine receptors in pituitary and striatum to chronic neuroleptic blockade and short-term apomorphine exposure.

METHOD

Male rats were maintained on a graduated dosage of haloperidol, beginning with 0.32 mg/kg twice daily for 4 days. This was followed with 0.64 mg/kg twice daily for 4 days, and 1.25 mg/kg twice daily for 4 days. Finally, the animals received 2.5 mg/kg twice daily for 8 days. A second (control) group was maintained on the vehicle of tartaric acid in water. All injections were intraperitoneal and the total drugging period was 20 days. On the 7th day after the last injection, animals were injected with 0.08 mg/kg of apomorphine, 0.32 mg/kg of apomorphine, or a vehicle of 0.1% sodium meta-bisulfite (an antioxidant) in water. They were killed by decapitation 30 minutes later, and pituitaries were immediately removed and frozen on dry ice. Brains were also removed and cooled on ice. Later, at the completion of the procedure (about 2 hours), striata were removed and frozen at −20° C.

The dopamine receptor assay was carried out according to the method of Seeman and associates (12, 21). This assay measures the binding of tritiated haloperidol or apomorphine to membranes and uses the positive (active) enantiomer of butaclamol to define nonspecific binding. The specific component of binding can be calculated as that amount of tritiated ligand bound in the absence of (+)-butaclamol minus that bound in the presence of (+)-butaclamol. For homogenization and assay, striatal and pituitary tissue were pooled within groups. The results are stated as femtomoles per milligram of protein. For statistical analysis, we used a two-way analysis of variance and Student's t test.

RESULTS

The results of [^{3}H]haloperidol binding are shown in table 1. Chronic haloperidol administration caused an 18.3% increase in [^{3}H]haloperidol binding in striatum ($p=.003$). However, a 54.8% decrease in binding occurred in pituitary ($p<.001$). Exposure to apomorphine 30 minutes prior to decapitation did not significantly alter binding in striata of either normal or haloperidol-pretreated rats. However, in pituitary an interaction effect appeared; that is, the influence of apomorphine on receptor number was altered significantly by pretreatment with haloperidol. Apparently in pituitary, short-term apomorphine exposure causes a dose-dependent decrease in binding in normal rats but a dose-dependent increase in rats chronically maintained on haloperidol ($p=.004$).

TABLE 1
Specific [^{3}H]Haloperidol Binding in Rat Pituitary and Striatum

Experimental Conditions	[^{3}H]Haloperidol Binding (fmol/mg protein)			
	Rat Striatal Tissue*		Rat Pituitary Tissue**	
	Mean	SE	Mean	SE
No haloperidol				
No apomorphine	217.95	17.75	47.41	0.54
Apomorphine				
0.08 mg/kg	236.66	9.57	30.69	11.43
0.32 mg/kg	256.81	13.97	24.92	2.48
Haloperidol				
No apomorphine	292.39	6.97	21.42	0.61
Apomorphine				
0.08 mg/kg	280.01	16.69	38.16	6.31
0.32 mg/kg	268.86	17.91	46.94	4.42

*Each experimental group represents 9–12 determinations made on approximately 7 animals.
**Each experimental group represents 3 determinations made on approximately 14 animals.

Animals treated chronically with haloperidol showed a 20.6% increase in butaclamol-specific [^{3}H]apomorphine binding in striatum (14.99±0.98 versus 18.08±1.13 fmol/mg of protein, $p<.05$). However, binding decreased in pituitary by 42% (10.68±0.75 versus 6.19±0.15 fmol/mg of protein, $p<.05$). In striatum both experimental groups represent 23 determinations each from 13 animals. In pituitary both experimental groups represent 2 determinations each from 9 animals.

DISCUSSION

The finding that chronic haloperidol treatment will produce an increase in specific [^{3}H]haloperidol binding in striatum is not new (22). Burt and associates (23) have reported that not only haloperidol but other antischizophrenic drugs such as fluphenazine and reserpine can increase striatal [^{3}H]haloperidol binding, apparently by an increase in receptor number rather than an increase in receptor-ligand affinity. The increase in specific striatal binding with chronic haloperidol treatment provides an explanation of the supersensitivity to apomorphine observable in rats following chronic neuroleptic exposure (24) and the development of striatal dopaminergic hyperactivity, seen clinically as choreiform movements, during chronic neuroleptic therapy. However, the receptor regulatory factors in pituitary tissue seem to be different from those in striatal tissue, since the response of [^{3}H]haloperidol binding in pituitary tissue to haloperidol exposure is opposite from that in striatal tissue. In the present study, we did not determine whether the observed changes in binding are a result of changes in receptor

number or avidity. Differences between the tuberoinfundibular-pituitary dopamine system and the striatal system have been observed previously. Schmidt and Hill (25) were able to detect dopamine-sensitive adenylate cyclase in striatal but not pituitary tissue. Also, haloperidol increases dopamine turnover in the corpus striatum but not in the median eminence, indicating that regulatory mechanisms in the dopaminergic neurons differ in the nigrostriatal and tuberoinfundibular systems (26).

Creese and associates (27) have suggested that the dopamine receptor exists in either an agonist or antagonist state. Agonists of dopamine would display a higher affinity for the agonist state receptors, and antagonists of dopamine would display a higher affinity for antagonist state receptors. For this reason we were interested to see if the receptor-binding changes measurable with [^{3}H]haloperidol were a reflection of an entire pool of dopamine receptors or just those in the antagonist state. Since we observed similar changes using either the dopamine antagonist, [^{3}H]haloperidol, or the dopamine agonist, [^{3}H]apomorphine, we concluded that the alteration in binding after long-term haloperidol administration involves both agonist and antagonist state receptors.

The prompt changes in pituitary [^{3}H]haloperidol binding observed with brief exposure to apomorphine indicates that pituitary tissue is capable of rapidly modifying either the number or affinity of dopamine receptors. Furthermore, the history of the pituitary is critical in determining the direction in which the receptors will be modified in response to a stimulus. In contrast, receptors in the striatum do not seem to be acutely modifiable by apomorphine.

It appears that pituitary dopamine receptors differ from striatal dopamine receptors, and therefore the tuberoinfundibular-pituitary dopamine system may be a poor model for the nigrostriatal system. Whether there are major differences between the mesolimbic dopamine receptor, which is probably involved in schizophrenia (28), and the tuberoinfundibular-pituitary dopamine receptor remains to be determined.

Psychiatric and Neurologic Sequelae of Infectious Mononucleosis

BY NELSON HENDLER, M.D., M.S., AND WILLIAM LEAHY, M.D.

Infectious mononucleosis is usually thought to be a benign disease with occasional neurologic sequelae. Depression, incoordination, a reduction in intellectual ability, and altered EEG patterns were found in two patients; one recovered and the other seemed to have permanent residual effects. The possibility of tranylcypromine as a treatment for the depression and appropriate counselling of patient and family are discussed.

INFECTIOUS MONONUCLEOSIS (IMN), considered to be a disease of adolescence, presents as a febrile illness associated with lymphadenopathy, hepatosplenomegaly, pharyngitis, malaise, and myriad other complaints. The yearly incidence for this normally benign disease is 38 per 100,000, and 1 per 3,000 of these patients dies, usually as a result of neurologic complications (1). Nonfatal central nervous system involvement was first reported in 1931 (2), and reviews since then have reported a wide spectrum of neurologic dysfunction including meningoencephalitis (3, 4), encephalitis (5–7), the Guillain-Barre syndrome (8, 9), and mononeuritis (10). Schnell and associates (11) found one case in which neurologic findings were the only presenting symptom of IMN, and Bonforte (12) has reported convulsions as a presenting sign. Occasionally, personality changes such as irritability, emotionality, asocial behavior, and destructiveness have been described (13). Rapid and complete recovery from such involvement has been the rule; however, Cadie and associates (14) found that 13 of 20 women suffered depression and anxiety for as long as 1 year after IMN. We found prolonged neurologic and psychiatric consequences in the following two cases, one with confirmed and the other with presumptive sequelae of IMN.

CASE REPORTS

Case 1. John, a 14-year-old male, reported an inability to concentrate, a loss of athletic ability, a feeling of depression, irritability, and suicidal ideation for 5 months, ever since an attack of IMN, documented by a positive mono spot test, lymphadenopathy, splenomegaly and tenderness, general malaise, leukopenia, and fatigue. Before contracting IMN, he was well adjusted socially, and his only major medical illness was thyroiditis 4 years earlier.

John's father is a prominent physician, and his mother is a housewife and part-time nurse. His mother had hypothyroidism, and a maternal aunt had a 1-year depressive episode. His developmental history was normal, with an absence of both febrile convulsions and dyslexia. John's mental status examination showed that he had no difficulty with concentration, memory, or recall. The neurologic examination was normal. An EEG revealed diffuse slow activity (2–7 cps) and diffuse low voltage, fast activity (15–25 cps). At the start of therapy, his verbal IQ was 145, but his performance IQ was 112.

Initially, John was placed on imipramine, 150 mg h.s., and sodium liothyronine (Cytomel), 25 mg every morning for 1 month; no improvement was noted. Imipramine was discontinued, and he was then placed on tranylcypromine, 20 mg b.i.d., which improved his concentration and eradicated his depression. After 2 months, John wanted to discontinue medication. Within 1 week, he was again depressed, suicidal, and had difficulty concentrating. The medication was reinstituted, and within 2 weeks John felt better. He was maintained on tranylcypromine, 15 mg b.i.d., for an additional 2 months.

In therapy, John talked about the guilt associated with his poor school performance, his anger about the disability created by the IMN, and his frustration at the inability to control his concentration and motor skills. Repeated psychological testing 9 months after the initial visit resulted in a verbal IQ of 147 and a performance IQ of 131. This marked improvement in perceptual motor tasks, paralleled by a change in school performance from a D level to his previous honor role status, was accompanied by a normal EEG. There were no residual signs of depression, and his motor skills at the end of treatment had returned to his premorbid level.

Case 2. Jane, a 16-year-old single high school student, presented with the chief complaint of "I want to die and life is not worth living." She was admitted to an inpatient psychiatric unit after a suicide gesture. Her psychiatric disturbance began when Jane contracted mononucleosis at age 9. She was out of school for 5 months and failed a grade after she returned. The IMN precipitated reduced concentration, ability to perform calculations, and general difficulty with school work. She also reported that her fine motor coordination was greatly impaired after the disease.

Jane attributed her difficulty at home to the fact that both her mother, a dance teacher, and her father, a prominent lawyer, were pressuring her to do well in school. She felt guilty because she could not live up to their expectations. Her psychiatric and developmental histories were unremark-

Dr. Hendler is Clinical Director, Mensana Clinic, Greenspring Valley Rd., Stevenson, Md. 21153, and Assistant Professor of Psychiatry, the John Hopkins Hospital, Baltimore, Md., where Dr. Leahy is a resident, Department of Neurology.

0002-953X/78/0007-0842$0.40 © 1978 American Psychiatric Association

able, and she had been a well-adjusted child until the onset of IMN.

The pediatrician who diagnosed IMN documented the disease by obtaining a heterophile titer, which was 1/320 initially, progressed to 1/1792 10 days later, and was accompanied by lymphadenopathy, hepatosplenomegaly and tenderness, SGOT of 148 IU, and lymphocytosis. There is no family history of thyroid disease, diabetes, alcoholism, or mental illness. On physical examination, there was some questionable asymmetry of pupil size, the left side being slightly (1 mm) larger than the right, minimal dysdiadochokinesis, minimal ataxia, and some difficulty with tandem walking. She had a fine, bilateral intention tremor, and mildly increased deep tendon reflexes on the left. EEG showed a great deal of diffuse low voltage activity (15–25 cps) and considerable amounts of diffuse low to medium voltage activity (2–7 cps). Echo results were suggestive of an enlarged right lateral ventricle, and cerebral mantel thickness measured 2.6 cm on the right and 3.4 cm on the left. The mental status examination revealed that her concentration, memory, and recall were intact. She admitted to feeling depressed but denied any vegetative signs of depression. She had a verbal IQ of 104 and a performance IQ of 104. Family therapy centered around convincing her parents that their expectations for Jane were somewhat unrealistic in light of her intellectual and motor functioning, which probably resulted from the IMN and not from rebellion. Once the parents recognized that their hopes for Jane might have been in excess of her abilities and eased their pressure on her, Jane reported feeling more relaxed and less depressed. Three years later she finished high school and is now living comfortably with her husband.

DISCUSSION

There are some similarities between these two cases that are worthy of recognition. Both children had good premorbid adjustment, good grades in school, and supportive family situations. Both patients felt that their psychiatric difficulties began after they contracted IMN, and both reported difficulty with concentration, fine motor activity, and with understanding what had wrought the changes in their mental functioning, physical skills, and personality. Both had reported depression after their bouts with IMN. Both suffered dramatic changes in their school work, which compounded their depression. Both came from upper-middle-class, achieving families and regarded impaired intellectual functioning as disastrous. Both had minimal, if any, significant localizing neurologic signs, and both had 2–7 cps diffuse low to medium voltage activity and 15–25 cps diffuse low voltage fast activity on their EEG. Both had reduced IQ scores, although one score was transient and the other could have been due to other causes.

Viral diseases (such as cytomegalovirus) may produce a wide spectrum of psychiatric disturbances, varying in both intensity and duration (15). Anxiety and guilt reactions are most commonly appreciated (13); more devastating stages range from confusion, delirium, and affective psychoses to the more profound "toxic organic" psychoses associated with severe mental disturbance and coma (16). Lipow[illegible] 17) m. Imboden (18) have advanced the notion [illegible] psychological variables determine the length of re[illegible] course of IMN. Slow recovery has been associate[illegible] with g scores of ego strength (19), and since the [illegible] closed environment is also changed by an infect[illegible] psychosc "there is a tendency for the observed symp[illegible] to be strongly tied to the premorbid perso[illegible] ture upon which the disease impinges" ([illegible] 20 noted that some conduct disorders occu[illegible] are similar to minimal brain dysfunction, and [illegible] 21 and Cadie and associates (14) reported [illegible] experienced anxiety and depression after [illegible] and associates (14) also noted an increas[illegible] symptoms after IMN. This increase in [illegible] pression, and somatic concern is not unlik[illegible] seen in most people with a chronic illne[illegible] 2[illegible].

Neurologic sequelae of IMN have been [illegible] sively described. EEG abnormalities ha[illegible] ported in acute cases of IMN (11) and s[illegible] range (4–7 cps) activity in either paroxys[illegible] continuous patterns. However, several of [illegible] ported had diffuse activity ranging from 1-[illegible] the early phase of the illness (days 1 to 2[illegible] our patients, theta activity (2–7 cps) wa[illegible] both patients also showed diffuse low vo[illegible] (15–25 cps), as well as unstable posterior [illegible] um voltage (8–10 cps) alpha rhythm; how[illegible] the EEGs were obtained after the acute p[illegible] Localizing, unilateral neurologic findings [illegible] reported, manifesting as weakness a[illegible] clumsiness in the use of hand and foot (2[illegible] eral Gordon and Chaddock reflexes (24) [illegible] of ataxia, slurred speech, decreased abili[illegible] trate (25), and disorientation (7) have also [illegible] ed. Silverstein and associates (26) report[illegible] neurologic complications are the first a[illegible] signs of IMN, some of which, like metam[illegible] "Alice-in-Wonderland" syndrome, may [illegible] as drug-induced states or psychiatric d[illegible]

Some authors (3, 26) have report[illegible] volvement as a heralding feature of the [illegible] others (10) find that CNS involvement [illegible] the acute illness and note that the neuro[illegible] ten may predominate or obscure the usu[illegible] systemic symptoms. The incidence of ne[illegible] function in IMN varies, but most author[illegible] mately a 1% rate. One-year follow-up in [illegible] hensive series (1, 26, 28) showed rather r[illegible] plete recovery from IMN. However, the [illegible] have presented reveal that persistent ne[illegible] function, as well as mental aberrations, m[illegible] though a reactive depression in respons[illegible] likely consideration, an organically [illegible] ponent, secondary to CNS involvement, [illegible] bility. Intellectual, depressive, and mot[illegible] ities should not be dismissed on the bas[illegible] reactive and/or volitional component (co[illegible] conscious).

Understanding that family as well a[illegible]

pectations may need to be altered as a result of CNS involvement secondary to IMN may significantly help the patient to accept difficulties that he or she experiences. Unrealistic expectations, or assigning psychological interpretations to a physiological response, can create undue stress on the patient. Reassurance of patient and family are necessary to ensure a successful treatment for the depression (no matter what its etiology) associated with IMN. The monoamine oxidase inhibitor tranylcypromine may also be useful in the treatment of post-IMN depression, in part because of its amphetamine-like structure, although its mechanism of action is due to presynaptic accumulation of norepinephrine. This suggests that the CNS involvement after IMN is similar to minimal brain dysfunction, since both conditions respond to amphetamine-like substances, are associated with difficulty in school, and may be secondary to viral diseases that affect the CNS.

A National Survey of Resident Assessment Methods

BY WARREN PROCCI, M.D., CLAUDE FRIEDMANN, M.D., GILLA PRIZANT, M.D., AND SHERWYN M. WOODS, M.D.

The authors distributed a questionnaire regarding the assessment of psychiatric residents to 130 directors of residency training programs. Formal examinations were required by 37% of the programs and were being considered by an additional 49%, suggesting that formal examinations may be an integral part of residency training programs within five years. The authors believe that this trend toward utilization of objective measures reflects a growing national concern with accountability in medicine.

ONE OF THE notable developments in medicine during the 1970s is the emphasis on accountability. Psychiatry is not exempt from it (1–3), witness the recent decision by the American Psychiatric Association (4) to require evidence of continuing education for maintenance of membership. Similarly, many states now require such education for maintenance of licensure. The American Board of Psychiatry and Neurology, Inc., (ABPN) is currently studying the feasibility of recertification procedures for psychiatrists, and the Group for the Advancement of Psychiatry (GAP) (5) has suggested that Part I of the ABPN examination be given before graduation from residency programs.

It is organized psychiatry's responsibility to insure quality control, not only of practitioners, but also of residents in training. Although such formal self-scrutiny has not previously been characteristic of the medical profession, it has now become a necessity (6). It has been pointed out (7) that the training of competent psychiatric clinicians is both a matter of public concern and the primary responsibility of the psychiatric educational community. This goal is achieved in part by the assessment of the educational quality of residency programs, which is essential because it helps to assure requisite educational opportunities for becoming a qualified specialist. However, the presence of adequate educational opportunities in no way ensures that individual residents will use them. An important question then is to determine the means by which programs decide whether residents have acquired necessary skills. We undertook this study to [illegible] following two questions: 1) What me[illegible] programs currently use to determine a[illegible] formance? and 2) What changes, if any[illegible] anticipate making in the next five years?

METHOD

A 12-item questionnaire was distribute[illegible] bers attending the 1976 Annual Meeti[illegible] can Association of Directors of Psychi[illegible] Training (AADPRT).[1] A follow-up m[illegible] responders and members not in atten[illegible] ducted two months later.

Each program director was asked to [illegible] lowing: program name, geographic loca[illegible] cility, number of residents, number of f[illegible] ment methods currently used, weight [illegible] method, any exams used and their n[illegible] sequences, persons involved in plann[illegible] methods, and any contemplated change[illegible]

RESULTS

Responses were obtained from 1[illegible] 176 residency programs listed in the A[illegible] bership. Response rates did not differ a[illegible] geographic areas (South, West, North[illegible] east, Mid-Atlantic). Not all respon[illegible] each item in the questionnaire, so the [illegible] item does not necessarily equal 130. T[illegible] residents in the responding programs r[illegible] the case of several programs in planni[illegible] The number of full-time faculty in [illegible] ranged from 1 in a planned program t[illegible] in several large programs. Ninety-one [illegible] identified as primarily university progr[illegible] 39 programs, which were affiliated w[illegible] vate, and military hospitals, were consi[illegible] as nonuniversity programs.

Table 1 lists the evaluative methods [illegible] chiatric residency programs, the numbe[illegible] age of programs that used each, and th[illegible] ranks assigned by the training directors [illegible] ods they considered most important. Ta[illegible]

that 48 programs (37%) required formal examinations; it also shows how many programs allowed anonymity on exams and how they used exam results.

Some definite future change in the assessment process was contemplated by 101 of the programs (78%); the changes planned are summarized in table 3. Since some programs had multifocused designs, the total number of items in the table exceeds the number of respondents.

University and nonuniversity programs were compared on the following items: techniques of assessment used, use of techniques to evaluate progress, changes planned in assessment techniques, personnel involved in planning resident assessment, whether exams were voluntary, whether anonymity was allowed on examinations, and the use of a variety of examination modalities (e.g., direct observation of resident interviews, APA Self-Assessment Examination, etc.). There were no significant differences between university and nonuniversity programs.

Similar analyses were conducted for the various geographic regions and for program size. No consistently significant patterns were noted.

DISCUSSION

This study indicates that assessment practices in psychiatric residencies are relatively uniform across program type, size, and location. Written evaluations by clinical supervisors and unit chiefs, relatively subjective forms of evaluation, are emphasized currently. Formal written or oral examinations, which are considered more objective measures, were used much less frequently, but many programs were planning to implement such techniques. If these plans actualize, we predict that within the near future such exams will be an integral part of the assessment procedure in virtually every program. We can speculate that this trend toward increased utilization of objective measures is at least in part a response to the growing concern with accountability (5, 8).

A quarter of all programs responding (N=33) gave involuntary, nonanonymous examinations that were used in evaluating resident progress. The consequence of poor performance on such examinations was most commonly remedial work, but in some programs poor examination performance resulted in repetition of a training year or even termination from residency. Since the number of programs using examinations is likely to increase in the near future, an increasing number of residents may find such accountability awaiting them during their years in training.

It is interesting to note that 25% (N=33) of the programs polled indicated that they were currently using or planning to use the APA Self-Assessment Examination as an evaluative method. This indicates that with the encouragement of a professional organization new and innovative assessment methods can be made available and acceptable to a large portion of its membership. Such leadership can provide impetus for the profession as a whole in the "interwoven issues of lifetime education, government supervision, and the constant updating of knowledge" (9).

With any such shift in emphasis, there is always a possibility of overemphasis, especially if the presumably quantifiable and objective results of these examinations are seen as a path of least resistance for as-

suaging the need for accountability. At best, a formal written examination measures a certain cognitive data base but in no way measures a variety of other skills, such as the ability to conduct an interview, elicit pertinent data, and formulate a diagnosis based on those data. These skills are obviously also important for a psychiatric trainee to possess. Similarly, other forms of examination have limitations (10).

Another caveat of giving examinations is that overemphasis on apparently objective measures, especially if other methods are ignored, may result in a uniformity of product and a stifling of creativity. Also, it is very difficult to correlate examination performance with performance in actual clinical practice (11–13). Therefore, we would urge programs to consider the use of a wide variety of assessment methods that would emphasize a more global approach to the evaluation of resident skills (14).

The importance of clarifying educational goals for residents early in their training has been stressed (11, 15). Examinations without clarification of objectives may well lead to their being viewed as threatening rather than as a measure of mastery. Although the establishment of goals and objectives is a worthwhile endeavor that has long been neglected, this process does have limitations. Difficulties may arise if the resident views such goals as comprehensive rather than as guidelines. Of course, it would be unrealistic to assume that the educational process is complete when specified objectives are attained.

Change is often met by resistance, and the degree of resistance is directly related to the distance between those experiencing the change and those establishing it. A majority of the programs polled involved residents in assessment planning (N=85) but a sizeable number did not. Smooth implementation of new evaluative methods in residency training programs is likely to occur if there is meaningful participatio[illegible] by the residents involved. We hope that [illegible] pation during residency will provide the [illegible] tive involvement in professional accoun[illegible] one's entire career. Lest psychiatry beco[illegible] with government and lay regulatory [illegible] default (7, 8), such an active role is oblig[illegible]

The Children's Psychiatric Hospital Unit in the Community: I. Concept and Development

BY BARTON J. BLINDER, M.D., WILLIAM M. YOUNG, M.D., KENNETH R. FINEMAN, PH.D., AND STEPHEN J. MILLER, M.A.

The authors describe a children's mental health unit (CMHU) in a general hospital and cite the need for short- and intermediate-term children's psychiatric facilities within the community. They point out the special need for psychiatric inpatient units for the 3–13 age group and note that in their CMHU the average length of stay and patient turnover ratio compare favorably with adolescent units, which they attribute to the emphasis on diagnosis and treatment rather than long-term rehabilitation.

RECENT STUDIES (1–5) point to the increasing need for short- and intermediate-term children's psychiatric hospital units in the community. Von Mering and Carpenter, as cited in the 1970 report of the Joint Commission on Mental Health of Children (2), emphasized the need for timely, specialized community child mental health services that include centers for the treatment of autistic children, therapeutic nurseries for the evaluation of complex developmental problems, and centers for more comprehensive diagnosis and treatment of atypical ego development in children.

The lack of comprehensive child mental health services leads to delayed detection of more serious deviations in child development, which results in complex adverse consequences for the emerging individual and for society. Often families experience ambiguity in the diagnostic efforts of unintegrated services, which interferes with effective intervention (5).

Portions of this paper were presented at the 26th annual meeting of the American Association of Psychiatric Services for Children, New York, N.Y., Nov. 20–24, 1974, and at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Drs. Blinder and Young are Assistant Clinical Professors of Psychiatry, and Dr. Fineman is Assistant Clinical Professor of Medical Psychology, Department of Psychiatry and Human Behavior, University of California, Irvine. Mr. Miller is a doctoral candidate in Professional Psychology at United States International University. Send reprint requests to Dr. Blinder at 17822 Beach Blvd., Suite 437, Huntington Beach, Calif. 92647.

The authors wish to express their appreciation to Gilbert Morrison, M.D., Dane Prugh, M.D., and Eveoleen Rexford, M.D., for their critical comments; to E. James Stanley, M.D., and Janice Del Fiaco, M.A., for their role in the founding of the CMHU and to Robin Baker and Judith Goldner for their administrative and editorial assistance.

Despite efforts by individual agencies and clinicians, few children identified as needing mental health services receive them. Von Mering and Carpenter (2) estimate that, of the 93 million young people (under age 24) in the United States, 1 to 3 million are seriously disturbed and identified as mentally ill or impaired. An earlier study (6) of inpatient treatment reported that facilities exist for approximately 7% of youths who require treatment.

THE CHILDREN'S MENTAL HEALTH UNIT

Location

The purpose of this article is to define a children's psychiatric inpatient unit in a community general hospital that provides easily accessible diagnosis and treatment of children without resorting to a more formal psychiatric institution. Our model is the Children's Mental Health Unit (CMHU) at Huntington Intercommunity Hospital in Huntington Beach, Calif., founded in 1973. The extreme pressure of population growth, the high youth-dependency ratio, the lack of coordinated diagnostic and therapeutic services for children, and the reasonable availability of funding sources render this area a laboratory for innovations.

Staff

The attending psychiatric staff at CMHU consists of 5 child psychiatrists who provide the administrative direction and medical supervision of all admissions to the unit. The CMHU team is comprised of a child psychiatrist, consultant pediatric neurologist, pediatrician, clinical and educational psychologist, special education staff, art therapist, consultant speech and language pathologist, psychiatric social worker, and nursing staff. Members of the multidisciplinary team collaborate in formulating a treatment plan appropriate to the physical and emotional needs of each child.

Indications for Admission

The CMHU offers a range of treatment programs. For example, a short-term stay of 1 week might be appropriate when a family disaster results in a posttraumatic reaction in the child. Crisis intervention may be required for child and adolescent suicide attempts or episodes of antisocial acting-out. A longer period of hospitalization (3–6 weeks) might be appropriate for

0002-953X/78/0007-0848$0.45 © 1978 American Psychiatric Association

children who require careful diagnostic evaluation and some longitudinal observation; this category includes borderline psychotic children, children with seizure disorders and secondary behavioral difficulties, and children with cerebral dysfunction that requires careful delineation and control. Longer term admission for 3 months might be appropriate for stabilization and more intensive treatment of the acutely psychotic child. Reevaluation and assessment of the chronically psychotic or autistic child might be required to establish maximum educational milieu intervention in addition to efforts for appropriate placement. Reconstructive milieu treatment would be useful in helping to resolve a period of acute, severe preadolescent turmoil or in interrupting a deteriorating child-parent relationship.

These situations are a sample of disorders for which an inpatient unit for children within a community general hospital can serve usefully and appropriately. Other conditions that represent potential admissions are early detection of developmental deviation and developmental delay in the first 5 years of life (these admissions might be coordinated with concomitant day care therapeutic nursery programs); complex juvenile diabetes; and such entities as juvenile colitis, rheumatoid arthritis, asthma, obesity, and anorexia, or more rare entities, such as compulsive tic and dysautonomia. If the CMHU were located in a large children's hospital, the incidence of psychophysiological disorders would probably be higher.

Characteristics and Disposition of Patients

Of 117 patients admitted to the Huntington CMHU between April 1973 and April 1975, 91 (78%) were boys and 26 (22%) were girls. In addition, 7 boys were readmitted. The average length of stay was 51 days (range 4–225 days), and the mean age was 9.7 years (see table 1). Patients with discharge diagnoses of personality disorder, developmental disorder, and reactive or crisis disorder accounted for 65% of the admissions[1] (see table 2). The relatively small number of psychotic disorders (10%) may be representative of the incidence of psychosis among referred children in the community at large. The availability of alternative diagnostic and treatment facilities in the area (table 3) has limited the admission of children with primary mental retardation.

Table 3 refers to the discharge disposition of patients at CMHU. Seventy-two percent returned home. Another 10% were placed in foster or group homes, and 7% entered programs in residential [illegible] ities. The CMHU offers short- and inte[illegible] intervention in a setting close to the hom[illegible] criteria for community psychiatric servi[illegible] immediate intervention, and discharge [illegible] setting).

[1]In the "personality disorder" category the largest number of children fit into the "unsocialized aggressive" category. "Developmental disorder" refers to developmental hyperactivity and variants of developmental delays and deviations, including atypical ego development. "Reactive or crisis disorder" includes children who were from pathological family environments (involving deprivation, abuse, and difficulties in limit-setting) or were undergoing reactions to sudden disruptions, such as the death of a parent or sibling, physical illness, or moving. In the "reactive or crisis disorder" category we saw 1 terminal patient who was admitted postoperatively with craniopharyngioma; he was admitted because of severe hyperphagia and a reactive behavior disorder.

DISCUSSION

Community Needs

In 1971 psychiatric hospital units fo[illegible] counted for an estimated 9% of all inpati[illegible] sodes among children under 18 in state, c[illegible] ty hospitals (4). A typical inpatient treat[illegible]

children and adolescents has fewer than 50 beds; is city, county, or state operated; and admits either adolescents only or both children and adolescents. Significantly, only 8% of psychiatric inpatient units restrict their admissions to children under 13. Therefore, less than 1% of all psychiatric episodes took place in what might be properly termed a children's psychiatric hospital unit.

The average age of admitted patients in the general hospital children's inpatient unit is 15, the average age in the children's psychiatric hospital unit is 13, and the average age in the residential treatment center is 14. This contrasts markedly with the average age in the CMHU described here—9.7 years. Clearly, there is a paucity of units devoted exclusively to the care of younger children, resulting in a restriction of adequate attention to their special needs. Appropriate program development for this group—age 3–13—constitutes a special need.

An Alternative to Residential Treatment Centers

Conclusions from the NIMH report on children's hospital units for emotionally disturbed children (4) indicated that general hospital inpatient units and children's psychiatric hospitals had fewer exclusions of suicidal and psychotic children than did residential treatment centers. This is appropriate due to the special status of the community unit as a resource for crisis intervention. The general hospital setting offers a wider variety of trained specialists for the assessment and treatment of the disturbed child than does the residential treatment center. Therefore, the hospital setting is more amenable to the diagnosis and treatment of the more complex and problematic cases.

The report noted that units restricting services to children had a longer length of stay and a slower turnover rate than did adolescent units. This has not been our experience. Our data indicate that the average length of stay (51 days) and the patient turnover ratio compare favorably with units restricting services to adolescents and are explained by the emphasis on psychiatric diagnosis and treatment as opposed to long-term rehabilitation.

A CMHU in the community appears to be an efficient service model representing the coordinated application of the highest level of professional training to both treatment-management planning and meaningful discharge and follow-up care.

Part II of this study will follow up children admitted to the CMHU in the areas of functional improvement, developmental progress, need for readmission, and need for reliance on longer term facilities.

CONCLUSIONS

The concept of residential treatment for children has evolved in part out of the necessity to remove the most severely disturbed children from their families and community. The roots of many existing institutions derive from foundling homes, orphanages, and religious and charitable homes for children and youths. The concept of community responsibility for the rearing of the child has been extended now to a concept of intervention in the child's development at critical junctures where family, school, and existing community support systems fail.

Since the end of World War II, the community general hospital has matured as an institution of service and leadership in providing comprehensive health care. The development of adult psychiatric inpatient services parallels that progress. At present, the majority of acute psychiatric admissions are referred to general and community hospital facilities.

For several reasons, there has not been a parallel development of inpatient facilities for children in the community. Ideologically, the child guidance clinic with its multidisciplinary-team approach has been home- and family-centered. Despite innovative outreach to schools and social agencies, significant intervention and comprehensive clinical data-gathering are inhibited by the appointment structure and recurrent problems in staff communication. Consequently, many seriously disturbed children and families are maintained for months and years without definite focus in all determinants of the clinical problem or referral to alternative management options (7). The available models for residential treatment have posed limits to our conceptualization, leaning primarily on state hospital units or various therapeutic residential schools located outside urban areas.

The community general hospital is a natural focus for a diagnostic and short-term child psychiatric treatment unit. Its advantages are 1) proximity to major population areas, 2) ready availability of large numbers of staff physicians and specialists for diagnosis and treatment, 3) easy accessibility to related social agencies, and 4) outpatient treatment programs for ultimate referral. The attending staff of child psychiatrists provides the same leadership as other medical and surgical specialties within the hospital and, in conjunction with the supporting staff, coordinate a meaningful diagnostic and treatment program. The major emphasis for any particular child may be on careful diagnostic delineation, intensive crisis resolution for child and family, redirection of an inadequate management and treatment program, and the setting of realistic limits and goals for the child's later development. These functions are unquestionably valuable and, unfortunately, are frequently not performed optimally in current existing models of child guidance centers, private outpatient treatment clinics, and individual practices.

Extrapyramidal Side Effects with Lithium Treatment

BY JOHN KANE, M.D., ARTHUR RIFKIN, M.D., FREDERIC QUITKIN, M.D., AND DONALD F. KLEIN, M.D.

The authors neurologically examined 38 patients who had received lithium carbonate for from 3 months to 5 years to determine the presence of extrapyramidal side effects. No patient had received neuroleptics for 3 months before examination. Definite cogwheeling was found in 2 patients. The results confirm previously reported occurrence of cogwheeling in lithium-treated patients.

LITHIUM CARBONATE, now an established treatment in the prophylaxis of certain affective disorders (1), continues to be applied experimentally in the treatment of other conditions (2). Considerable experience has been accumulated with regard to potential toxicity (3), yet the first report suggesting that extrapyramidal symptoms (EPS) might frequently occur with lithium treatment (4) appeared only recently.

Shopsin and Gershon (4) examined 27 patients taking lithium and reported that 15 of 20 patients on lithium for over 1 year showed evidence of cogwheeling. None of these patients had received neuroleptics during their lithium treatment. Intravenous administration of 4 mg of benztropine mesylate to 9 randomly selected patients with cogwheeling resulted in some improvement in 2 patients and no change in 7. (i.e., patients receiving lithium and patients receiving neuroleptics were examined). Patients were rated on the following 7 items from the Simpson Angus Scale (5): gait, arm dropping, shoulder shaking, elbow rigidity, fixation of position or wrist rigidity, tremor, and salivation. We added items for cogwheeling dystonia and akathisia and two items to assess akinesia (spontaneity of speech, gestures), all on a 5-point scale. Cogwheeling was measured by moving the patient's forearm while the patient remained relaxed in order to assess the amount of fluctuating resistance.

The sample consisted of 36 bipolar manic-depressive patients and 2 schizo-affective patients, diagnosed according to the *Research Diagnostic Criteria* of Spitzer and associates (7). Seven patients were receiving imipramine (range, 50–250 mg/day) in addition to lithium carbonate. Two patients were receiving diazepam up to 10 mg/day.

Patients were receiving a mean lithium dose of 1300 mg/day (SD, 396; range, 900–2700). The mean serum lithium level was 0.79 mEq/liter (SD, 0.22; range 0.50–1.30). Mean duration of lithium treatment was 15.6 months (SD, 13.2; range, 3–60).

RESULTS

Of the 38 patients examined, only 2 manifested evidence of cogwheel rigidity, and both of them manifested additional signs of extrapyramidal disorder, although of minor significance. The most frequent positive rating was for tremor (N=17), which was fine and rapid and usually of mild to moderate severity. Several of the patients with tremor were subjectively unaware of it before the examination. Few patients complained of drug side effects. Neither of the 2 patients exhibiting cogwheel rigidity were receiving any medication other than lithium carbonate.

One patient received several abnormal ratings (gait, +1; arm dropping, +3; elbow rigidity, +2; wrist rigidity, +2; tremor, +3; and akathisia, +1). None of these abnormalities responded to benztropine mesylate, 2 mg I.M. We referred this patient for further neurologic workup, which led to a diagnosis of normal pressure hydrocephalus. This was the only patient who received ratings greater than 1 on any item other than tremor or cogwheeling.

Six other patients received ratings of 1 on the following items: akathisia (N=2), spontaneity of speech (N=1), wrist rigidity (N=1), arm dropping (N=1), and gait (N=1). We feel that scores of 1 are not clinically significant and cannot be considered as definite abnormalities. One patient with +1 akathisia was receiving 100 mg/day of imipramine and the patient with +1 arm dropping was receiving 50 mg/day of imipramine.

We explored in great detail the medication histories of the 2 patients exhibiting cogwheeling with the patient, from chart review, and by contacting previous physicians. One patient had been exposed to neuroleptics for 6 weeks during the treatment of an acute manic episode, which had occurred 8 months before neurologic examination. This patient was reexamined on several occasions during the 6 months after neurologic examination, and the cogwheeling persisted at the same level of intensity. The patient did not experience a sensation of rigidity. The other patient had received several courses of neuroleptic treatment, including chlorpromazine, trifluoperazine, thioridazine, and fluphenazine decanoate. She had not received any neuroleptic medication for 5 months before neurologic examination. It is conceivable that, despite a 5-month interval, the last medication she had received, an injection of 25 mg of fluphenazine decanoate, contributed in some way to the development of persistent cogwheeling; however, the patient continued to manifest this sign 4 months after the original examination (i.e., 9 months after the injection). Neither of these subjects had a rating greater than 2 on any other item. Both patients were suffering from bipolar illness. The first was 19 years old and had been receiving lithium for 8 months (dose, 1800 mg/day; blood level, 0.8 mEq/liter); the second was 55 years old and had been receiving lithium for 20 months (dose, 1200 mg/day; blood level, 0.9 mEq/liter). Both were subsequently treated on two separate occasions with benztropine mesylate, 2 mg I.M., and examined 1 hour after treatment. Cogwheeling did not improve in either patient.

DISCUSSION

Our findings are consistent with those of Branchey and associates (6), who found cogwheeling in 3 of 36 patients receiving lithium carbonate. This report differs from previous studies in that our examinations were carried out by a rater blind to the patient's medication. Even in the physical examination of patients, considerable subjectivity and variation in interexaminer reliability occurs (8).

Our finding of a relatively high prevalence of tremor is consistent with the reports of others (4, 9). Since the tremor that occurs frequently with lithium treatment does not respond to antiparkinsonian drugs, it has been felt that the tremor is not related to the extrapyramidal system (3).

The occurrence of cogwheel rigidity, however, is surprising and difficult to explain. Although lithium has been reported to produce a variety of side effects (9), extrapyramidal involvement, except in toxic states, has rarely been reported. Despite its low prevalence, cogwheeling as a side effect of lithium treatment requires explanation. Further investigation of potential neurologic side effects with lithium treatment is of clinical and heuristic importance.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Psychiatric Illness in Relatives of Patients with Parkinson's Disease: An Expanded Survey

BY ANDREW WINOKUR, M.D., PH.D., JOHN DUGAN, JOE MENDELS, M.D., AND HOWARD I. HURTIG, M.D.

Several recent reports have suggested that there may be an association between Parkinson's disease and some forms of depressive illness (1–3). This prompted us to study the prevalence of affective disorders in first-degree relatives of patients with Parkinson's disease. It was proposed that the genetic factors predisposing to these two conditions might overlap, and that the lifetime prevalence of depressive illness in the first-degree relative of probands with parkinsonism might be greater than that in the general population. In order to test this hypothesis, a pilot study involving seven patients with Parkinson's disease was carried out, and a 24% frequency of primary affective disorder was observed in the first-degree relatives of these patients (4). On the basis of these data, we have studied a larger number of subjects but have been unable to replicate our previous findings of a high frequency of affective disorder in the relatives of patients with Parkinson's disease.

Method

Patients were selected from the Movement Disorder Clinic and the Neurology Group Private Practice of the Hospital of the University of Pennsylvania. The subjects were 25 consecutive patients who agreed to participate in the study, had minimal or no dementia, and had a first-degree relative available to accompany them for the interview. The patient, at least one first-degree relative, and, in many cases, the patient's spouse were interviewed together in a semi-structured format. Information was obtained for every first-degree relative regarding possible indications of affective disorder, schizophrenia, and alcoholism. Attempts were made to contact any living relative whose history was suggestive of affective disorder. Interviewed family members were diagnosed according to the *Research Diagnostic Criteria (RDC)* (5) and noninterviewed relatives according to the *Family History-Research Diagnostic Criteria (FH-RDC)* (6).

Results and Discussion

The 25 probands had a total of 113 male and 109 female first-degree relatives. Of these relatives, only 4 males (3.5%) and 7 females (6.4%) had clear histories of affective disorder. Even when the criteria for inclusion were eased to take into account relatives who had suggestive but incomplete histories of affective disorder, only 10 female relatives (9.2%) were identified. It should also be noted that few unequivocal cases of schizophrenia and alcoholism were encountered in these relatives.

It is reasonable to consolidate the data obtained from the 7 patients reported on previously with the 25 probands described in the current publication, since all 32 patients were obtained from the same clinic and were studied according to the same protocol. Information was thus available for a total of 138 female first-degree relatives of the 32 probands with Parkinson's disease. Fourteen of these female relatives (10.1%) had clear histories of affective disorders. Figures for the lifetime prevalence of depressive illness for fe-

males in the general population have been estimated to be as high as 9% (7).

Thus, even with the inclusion of the original probands in our total of 32 patients with Parkinson's disease, we are unable to substantiate the earlier suggestion that relatives of such patients might show a higher than expected lifetime prevalence of affective disorder.

Caffeine-Induced Delirium During Prolonged Competitive Stress

BY VERNER STILLNER, M.D., M.P.H., MICHAEL K. POPKIN, M.D., AND CHESTER M. PIERCE, M.D.

Excessive consumption of caffeine is a practice commonly used to overcome drowsiness and forestall sleep. Ritchie (1) has contended that dosages of 1000 mg of caffeine are capable of producing untoward reactions referrable in large part to the central nervous system. Such responses are said to entail restlessness and excitement, which may progress to mild delirium with sensory disturbances. McManamy and Schube (2) described a caffeine-induced psychotic state in a 1936 case report. Caffeine has also recently received attention as an etiologic factor in certain anxiety states (3). However, a review of the literature to date has not revealed other clinical reports corroborating Ritchie's contentions. This paper is a self-reported account of a caffeine-induced delirium (consistent with Ritchie's description) that occurred during a prolonged competitive stress situation.

Case Report

Mr. A, a 28-year-old single Alaskan fisherman and trapper, was entered in the 1977 Iditarod Trail International Sled Dog Race. The Iditarod spans 1,049 miles between Anchorage and Nome, following a route used decades ago by runners bringing diphtheria serum to Nome. Each March since 1973, "mushers" have proceeded overland by sled with dog teams for prize money (4).

Dr. Stillner is Director, Acute Admissions Unit, Alaska Psychiatric Institute, 2900 Providence Ave., Anchorage, Alaska 99504. Dr. Popkin is Assistant Professor of Psychiatry and Medicine, University of Minnesota Medical School, Minneapolis, Minn. Dr. Pierce is Professor of Education and Psychiatry, Faculty of Medicine and Graduate School of Education, Harvard University, Cambridge, Mass.

This work was supported by a grant from Roche Psychiatric Services Institute, Nutley, N.J.

The authors wish to thank the Iditarod Trail Committee and the racers.

In the third week of the 1977 competition, V[illegible]te an of two races, chose to mush continuously [illegible] h[illegible] 48 hours. He was only 2–4 days from Nome [illegible] he racers, was unwilling to yield time to sleep [illegible] ic, juncture of the race. Following an evening [illegible] of chops, two cups of brewed coffee, and three [illegible] resumed mushing in subzero temperatures [illegible] or winds. Despite this intake of an estimated 270–[illegible] ca feine (5) with his meal, he experienced increa[illegible] staying awake. Two hours after the meal, he in[illegible] of caffeine (2 tablets of Vivarin, an over-the-co[illegible] tion). Approximately 20 minutes later, he ing[illegible] tional 400 mg. Thus, in less than 3 hours he h[illegible] than 1000 mg of caffeine.

Half an hour later, he noted the emergence [illegible] re sion of several symptoms. His hands became t[illegible] he experienced a pronounced buzzing in his [illegible] ceived his miner's headlamp as emitting no m[illegible] row band of light. The ascent of a long hill se[illegible] were a flat plain riddled with white stars." V[illegible] and he tumbled twice from his sled in a sho[illegible] experienced doubt as to whether he was reall[illegible] feared being alone. This veteran driver, accus[illegible] cult conditions and sleep deprivation durin[illegible] managed to continue mushing. With the light[illegible] the passage of an interval of 6 hours (still wit[illegible] symptoms abated without subsequent diffic[illegible] rence. He arrived in Nome 3 days later and re[illegible] rience to one of us (V.S.) within hours of fin[illegible] status examination in Nome within 24 hour[illegible] pletion of the race revealed no aberrations and[illegible] A toxicology screen was negative. Complet[illegible] and blood chemistries were within normal lim[illegible]

Comment

In two previous races under similar co[illegible] ions th[illegible] man had used as much as 400 mg of caffe[illegible] b[illegible] form in 24 hours without untoward seq[illegible] t[illegible] 1977 race, within 30 minutes of serially c[illegible]

0002-953X/78/0007-0855$0.35 © 1978 American Psychiatric Association

proximately 1070 mg of caffeine, he noted a variety of symptoms. He experienced tremor, impaired memory, altered levels of consciousness, vertigo, pronounced anxiety, and sensory disturbances, including visual illusions and hallucinations. This picture is consistent with delirium (6).

With the advent of daylight after 6 hours, the symptoms fully remitted before he was able to warm himself or sleep. Hence, sleep deprivation or hypothermia appear insufficient factors to explain a transient and self-limited delirium. Rather, we believe the picture is likely best explained as a caffeine-induced delirium such as that suggested by Ritchie (1). The resolution of the delirium within a brief number of hours would not be inconsistent with the known half-life of caffeine in man following oral intake (7).

Mr. A neither smoked nor drank alcoholic beverages, and his medical and psychiatric history were unremarkable. He reported an average daily caffeine consumption of 270–360 mg. Psychiatric examination in Anchorage shortly before the race gave no evidence of any aberration. In addition, full pre- and postrace screening performed as part of an ongoing investigation of prolonged competitive stress (8) failed to reveal any striking abnormality in a battery of laboratory tests, including CBC, SMA-24, urinalysis, and several endocrine tests. There was no evidence of infectious process, and drug screening both before and after the race was negative, minimizing the likelihood of other toxic factors in the genesis of the delirium. Although other physiological contributors cannot be entirely excluded, it appears that the principal etiologic factor in the delirium was the excessive consumption of caffeine.

This case corroborates Ritchie's contentions about toxic effects of excessive amounts of caffeine and indicates that the common practice of using caffeine to stay awake may give rise to hazardous sequelae. As little as five 200-mg tablets of readily available over-the-counter preparations of caffeine appears sufficient to generate a delirium. Even smaller amounts may lead to sufficient sensory and motor disturbances to prove dangerous in situations such as long-distance driving. Such effects of caffeine merit closer attention.

Antagonism of Cocaine Highs by Lithium

BY ALVIN J. CRONSON, M.D., AND ABRAHAM FLEMENBAUM, M.D.

Beneficial effects of lithium treatment for amphetamine abuse were reported by one of us (A.F.) in two patients who spontaneously stopped abusing amphetamine while they were taking lithium because they no longer experienced the expected high. A third patient receiving lithium and amphetamines for weight reduction did not experience appetite suppression, highs, or the subjective effects of the amphetamines until lithium was discontinued (1). This concept was further supported by a placebo-controlled double-blind study of nine severely depressed patients. Lithium treatment resulted in a 60% reduction in their activation and euphoric responses to *d*-amphetamine and almost complete abolition of response to L-amphetamine (2).

There is a large body of evidence, both direct and indirect, regarding the beneficial effects of the use of lithium in amphetamine abuse, although the reports are still controversial (3–7).

Recently, Flemenbaum (8) demonstrated an inhibition of hyperactivity and stereotypic behavior in 10 rats (serving as their own controls) given doses of up to 19 mg/kg of cocaine. In this paper, we will report some clinical experiences that appear to support the hypothesis of an inhibition of cocaine highs by lithium.

Case Vignettes

Mr. A, a 28-year-old married man, had been detoxified from heroin and was drug-free. He was stabilized on lithium because he had symptoms of affective disorder. He reported

Dr. Cronson is Associate Clinical Professor and Dr. Flemenbaum is Associate Professor and Research Psychiatrist, Texas Tech University School of Medicine, Department of Psychiatry, P.O. Box 4569, Lubbock, Tex. 79410.

0002-953X/78/0007-0856$0.35 © 1978 American Psychiatric Association

he had obtained and used "pure coke" but had noticed no reaction. He had once taken cyclazocine and knew that it blocked the effects of heroin, and he asked whether lithium had a similar effect on cocaine.

Mr. B, a 25-year-old man, was on methadone maintenance, 90 mg/day. He was difficult to manage until he was started on lithium because of drug abuse and arrogant, manipulative, and impulsive behavior. He reported having no response to cocaine when he was receiving lithium, although his companions became "quite high on it."

Mr. C, a 28-year-old former addict and alcoholic, had been placed on lithium to control his mood swings, violent temper, and impulsiveness. He tried cocaine and found to his surprise that he had no reaction. He was grossly obese and thought that this would prevent him from getting a job, so he was given amphetamine on a careful experimental basis. He reported that while the amphetamine controlled his appetite, he felt no high and did not "crash" when the effects wore off, even if he took more medication than was prescribed. He lost 13.6 kg and was only 9.1 kg overweight when he completed treatment.

Mr. D, a 23-year-old single man with a diagnosis of manic depression, was placed on lithium with excellent results: he became stable in his interpersonal relations and employment and stopped abusing hypnotics and alcohol. He went to a Christmas party where a group of people were using cocaine. He had had some brief experiences with cocaine in college and looked forward to getting high, but he had no response to the drug, which "everyone else thought was great."

Ms. E, a 32-year-old single actress with a history of bipolar manic depression, had been diagnosed and successfully treated at several well-known lithium clinics. In spite of her good response, she had multiple rehospitalizations. During her most recent hospitalization, cocaine was discovered in her urine and her lithium level was negligible. Once stabilized, she confided that she liked the cocaine high but could not obtain it while she was taking lithium, so she had discontinued the lithium several times.

Discussion

Jefferson and Greist (3) have noted that "There is presumptive evidence in man that lithium can attenuate the activating and euphorogenic effects of amphetamine, but firm conclusions will not [illegible] until there are more well-designed studies."

Although our report is anecdotal, we [illegible] further illustrates the potential ability of [illegible] hibit drug highs. We recognize that the [illegible] this action may be indirect, i.e., by [illegible] masked affective disorder lithium may [illegible] creased need for the highs obtained from [illegible] We also recognize potential biases of non[illegible] tions, but we conclude that the evidence [illegible] support a potential use of lithium in the [illegible] drug abuse, including cocaine, and that [illegible] serves further scientific evaluation.

Bromism: Alive in Well

BY IRA BRENNER, M.D.

Bromism was first recognized 50 years ago, and reports abound to remind us that the entity persists (1, 2). In these reports, the source of the ion is usually traced to over-the-counter or prescribed medications (3, 4). To my knowledge, bromide intoxication from contaminated well water, as seen in the [illegible] scribe, has not been reported previously.

Case Report

A 51-year-old woman came to the emerg[illegible] cause of recurrent suicidal impulses, early [illegible] ening, anorexia, and increased alcohol cons[illegible] the previous week. She had not worked that [illegible] had an overwhelming sense of hopelessness [illegible] denied taking any medications, either prescri[illegible] counter. Her history revealed a 12-year epi[illegible]

Dr. Brenner is Resident, Department of Psychiatry, University of Virginia Medical School, Charlottesville, Va. 22901.

Dr. Brenner would like to thank Salman Akhtar, M.D., for help with the manuscript, and Susan Lazar, M.D., attending physician.

0002-953X/78/0007-0857$0.35 © 1978 American Psychiatric Association

alcoholism and depression that required four psychiatric hospitalizations for detoxification and supportive psychotherapy. The most recent hospitalization was 2 years before this admission. There were many stresses in her life, which were seen as precipitants. Previously, she had been diagnosed as having depressive neurosis with characterologic problems, and she had been treated with benzodiazepines. Her medical history included a hysterectomy 13 years previously. She had also sustained a concussion 3 months before admission in a single-car accident. She said she felt "down" at the time but denied suicidal intent. At that time, psychiatric consultation was not obtained and bromide levels were not assessed. Her family history included alcoholism in her father.

Mental status examination revealed a neatly dressed, friendly, alert, and oriented woman with mild restlessness, hand wringing, and a fine tremor. Her nihilistic feelings reached near-delusional proportions. She was apathetic and her affect was restricted to dysphoric expression. Her remote memory was hazy and inconsistent, although her recent memory and recall were grossly intact. Physical examination was unremarkable. Laboratory data, including thyroid studies, B_{12} level, and electrolyte and metabolic values, were essentially normal; the serum bromide was 38.3 mg/100 ml (normal, <5 mg/100 ml).

The patient's mood, affect, memory, and tremor improved quickly following hospitalization. In addition, serial bromide levels showed a decrease without medical treatment, returning to normal within 1 week and remaining at normal levels. Further questioning and history from other sources confirmed the patient's assertion that she took no medication and ate no unusual or treated foods. However, for the past 5 months she had used well water, which was assayed and found to have a bromide level of 2.1 mg/100 ml. (State regulations permit no bromide in drinking water, and the reason for the presence of bromide in the well remains unclear, although industrial wastes are suspected.) After her cognitive functioning and mood improved, she was able to work successfully on underlying dynamic issues during her 3-week hospitalization. She has had no recurrence of symptoms in 5 months of follow-up.

Discussion

The patient presented with an agitated depression. In addition, she displayed subtle evidence of bromide toxicity, including tremor and memory disturbance. She was exposed to the well water for 5 months before her admission, and moved after her discharge from the hospital. She had been using the well for 2 months before her auto accident, and one could speculate that bromide intoxication may have been contributory. Her bromism dissipated within a week without treatment. A return to normal blood levels in such a short time is unexpected, since the half-life of bromide has been reported to be about 12 days (5). However, in that study the dosage produced no symptoms, and "the amount of ammonium bromide administered to the subjects was considered to be sufficiently small as not to disturb the physiological distribution." The clinical applicability of such a study to subacute bromide intoxication is questionable, since other factors such as blood level and duration of ingestion might alter the excretion rate.

Our patient's highest recorded blood level was only 38.3 mg/100 ml, which is below the generally accepted range of toxicity. However, there is disagreement about toxic levels of bromide. Cut-off points range from 50 mg/100 ml (6) to 72 mg/100 ml (7), and some clinicians feel that mental status changes do not occur until even higher levels. A recent report of mania in a patient with a bromide level of 32.5 mg/100 ml (8) was criticized because of the relatively low blood level (9). Indeed, one might argue that our patient would have become symptomatic without bromide ingestion. However, dismissing the data as incidental is as presumptuous as ascribing a cause-effect relationship in such cases. It has been noted that "bromide schizophrenia" primarily occurs in women with premorbid schizoid personalities (4), and our patient may have been susceptible to subtoxic doses of bromide. Given her propensity toward mood changes, it seems reasonable to assume that she could become symptomatic at a lower than expected bromide concentration, whereas others using the well water remained asymptomatic.

It may be that our patient's threshold was decreased and bromide potentiated her characteristic depressive response to psychic stress. A constitutional or acquired biochemical defect that would allow subtoxic levels of the ion to interfere with neurotransmission of biogenic amines could exaggerate or precipitate mood changes in vulnerable people.

Psychotic Depression and Bronchogenic Carcinoma

BY JONATHAN G. SOLOMON, M.D., AND SANDRA SOLOMON, M.S.

This communication was prompted by a recent case in which a 51-year-old woman with manic-depressive illness, depressed type, presented with what appeared to be her fourth episode of psychotic depression. The episode was similar to her three previous episodes of affective illness, but medical evaluation unexpectedly revealed the presence of a bronchogenic carcinoma, which may have caused or contributed to her symptomatology. This case highlights the importance of medical evaluation of psychiatric patients.

Case Report

The patient, a 51-year-old rural housewife, had her first episode of psychotic depression when she was 35, her second at 39, and her third at 45. Each episode was characterized by depressed mood, anergia, anhedonia, sleep disturbance with early-morning awakening, difficulty in thinking, psychomotor retardation, feelings of hopelessness, loss of libido, and anorexia, with weight losses ranging from 6 to 12 kg. She had never been suicidal, delusional, hallucinatory, or paranoid. Medical history was negative except for her habit of smoking two packages of cigarettes daily. The family history was negative for affective illness and alcoholism. Each depressive episode responded to hospitalization and treatment with tricyclic antidepressants. Typically, she improved gradually over a 4–6 week period and was asymptomatic on discharge from the hospital. She was last discharged on imipramine, 150 mg h.s., but unfortunately refused maintenance chemotherapy "because I don't want to depend on pills." She declined periodic office visits and only consented to see a psychiatrist when her periodic depressive episodes occurred and became so severe that hospitalization was necessary.

Recently she complained of a fourth episode of depression. Her symptoms were similar to those of her three prior episodes and had begun approximately 3–4 months earlier without any evident precipitant. On admission she appeared cachectic, with marked pallor. Her appetite was poor and she had lost 10.2 kg. Psychomotor retardation was noted and she complained of feelings of depression, lack of energy and interest in living, and inability to function at home. There was no evidence of organicity and no history of drug or alcohol abuse. Her husband stated that this was a typical presentation, saying "This is the way she gets."

Routine medical evaluation revealed a hemoglobin of 8.6 mg and hematocrit of 26.0%. A chest film revealed the presence of a bronchogenic carcinoma with metastases. Consultation with an internist was arranged and the patient was transferred to the medical service for appropriate chemotherapy and radiation therapy.

Dr. Solomon is in private practice at Bayberry Hospital, 530 East Queen St., Hampton, Va. 23669; he is also Assistant Professor, Department of Psychiatry and Behavioral Science, Eastern Virginia Medical School, Norfolk, Va. Ms. Solomon is a Research Assistant with Dr. Solomon.

Discussion

This patient's clinical presentation w psychotic depression and occurred i three prior episodes of similar symptom is unwise to make a diagnosis solely o presenting symptomatology or psychi Medical evaluation is also necessary F uate this patient medically would have c priate diagnosis and treatment.

An organic lesion was not suspecte cause of the typical appearance of affect in a manic-depressive patient. A bronc noma was certainly unexpected in the a monary symptoms such as chest pain, d ness of breath, or hemoptysis. It is un this patient had another bout of affective tion along with the bronchogenic carcino er the malignancy caused or contributed toms, especially the anorexia, weight lo pallor, and anemia. She had not previou mic. Had she been receiving maintenan sant chemotherapy (1) an exacerbation ness would have been less likely to occ toms of weight loss, fatigue, and palle been more likely to be perceived as bei physical cause. Certainly these sympto sence of the psychiatric or emotional co pression would have alerted the clinic organic etiology. Although patients bronchogenic carcinoma often develo secondary to their illness, depression manifestation of a bronchogenic carc tinctly uncommon (2). Depression is tients with diagnosed carcinoma, presu of the realization of the gravity of the physical debilitation (3).

The differential diagnosis between organic illness can be difficult becau symptoms can be the initial manifesta pathology such as an occult malignan pancreatic carcinoma, retroperitoneal ly brain tumors, and of other illnesses, incl sclerosis, pernicious anemia, and endoc such as hyperadrenocorticism, hyperi hypothryoidism (4). Rossman (5) descri of cases in which depression dominate picture and delayed the diagnosis o orders; often, the lesion was an occult m reported that the erroneous diagnosis ease as emotional may occur because medical evaluation, the rarity of the illn vague complaints, the appearance of me before abnormal physical and laboratory

0002-953X/78/0007-0859$0.35 © 1978 American Psychiatric Association

or the coincidental occurrence of organic disease with psychiatric symptoms.

Wingfield (6) described several patients with unrecognized organic disease causing emotional symptoms that prompted the referral for psychiatric treatment. "Missed" diagnoses included epilepsy, multiple sclerosis, porphyria, neurofibromatosis, and amyotrophic lateral sclerosis. Stokes and associates (7) reported the following illnesses found on a psychiatric unit and initially misdiagnosed as psychiatric or functional: carcinoma, brain tumor, hypoglycemia, meningitis, thyrotoxicosis, myxedema, endocarditis, and pneumonia. Herridge (8) reported that 5% of patients admitted to the psychiatric unit of a general hospital suffered from a previously undiagnosed organic disease that was responsible for the psychiatric symptoms, and Saravay and Koran (9) found that 4% of psychiatric consultations in a large general hospital involved obvious organic disease erroneously diagnosed as psychiatric.

Psychiatrists would be well advised to adopt a holistic approach to patient care, including thorough medical assessment, especially for inpatients and for the frequent patient with affective symptoms.

"Spice Cabinet" Intoxication

BY ROBERT A. FAGUET, M.D., AND KAY F. ROWLAND, PH.D.

A recent clinical report (1) in this journal discussed nitrous oxide abuse by a 15-year-old boy who used aerosol cans of whipped cream to obtain the gas. Another equally dangerous high has come to our attention: nutmeg ingestion, which we have labeled "spice cabinet" intoxication.

Case Report

A 19-year-old student, after reading about the mind-altering properties of nutmeg in a popular "consumer's-guide" book about drugs, decided to experiment. He went to the kitchen spice cabinet, took down a can of ground nutmeg, and mixed a tablespoon of it with orange juice. The combination was distasteful, and he was able to consume it only with some difficulty.

Within 2 hours he was "in trouble." He felt flushed, dizzy, nauseated, and his mouth became parched. His heart pounded and a "tremendous" headache overcame him. Gradually his extremities became numb, his perception of time and space changed, and he became detached and restless. At one point he reported significant confusion and said he was "on the verge of visual hallucinations." Twelve hours later, after very little sleep, the intoxication was over, leaving him lethargic, achy, and subdued.

Dr. Faguet is Assistant Clinical Professor and Dr. Rowland is Staff Psychologist, Department of Psychiatry, Neuropsychiatric Institute, University of California, Los Angeles, 760 Westwood Plaza, Los Angeles, Calif. 90024.

Nutmeg is among the oldest spices in use. It is derived from the seeds of an aromatic evergreen tree, *Myristica fragrans*, which is native to the Spice Islands. Myristicine, the psychoactive ingredient, is found in the oil of the seeds and also exists in the seed coat, which is processed separately to produce mace. Nutmeg has been used medically as a stimulant and tonic for the stomach, but a 1525 account by Richard Banckes suggests its psychoactive properties: "To cleanse the brain of superfluous humours, take a quantity of maces and chew them well" (2, p. 98). For years, prison officials have known that inmates go on "nutmeg jags" when other drugs are unavailable.

Richard Evans Schultes, an early investigator of medicinal plants, described myristicine intoxication via snuffing. His first-person description is very much like the case reported here:

> The dose was snuffed at 5:00 p.m. Within 15 minutes, a drawing sensation was felt over the eyes, followed very shortly by a strong tingling in the fingers and toes. Then came a severe headache. Within half an hour, my feet and hands were numb. Walking became almost as difficult as when I had beriberi. I felt nauseated until 8:00 p.m. when I took to my hammock, overcome with drowsiness. Strangely, this was accompanied by muscular excitation, except in my hands and feet. About 9:30 p.m. I fell into a fitful sleep which continued with frequent awakening until

 0002-953X/78/0007-0860$0.35 © 1978 American Psychiatric Association

morning, when a strong headache continued until noon. A profuse sweating and, probably, fever persisted throughout the night. My pupils were strongly dilated during the first few hours of intoxication. Though performed under primitive conditions in the jungle, this experiment does, I think, indicate the great strength of the snuff. The larger dose used by the witch-doctors causes them to see visions in colors, which I did not experience. During their dreams, they emit wild shouts that are interpreted by their assistants. They admit that using this substance is a dangerous practice, one of their number from the Puivave tribe having died during Yakee intoxication. (2, pp. 99–100)

Nutmeg abuse can be serious. Not only are the psychic effects disturbing and dangerous, but poisoning and death due to fatty degeneration of the liver have been reported (2). Fortunately, in larger quantities nutmeg is unpalatable and the side effects
unpleasant. However, as in the case of th
student, advertisement in popular "dru
lead some young people to experiment.

Selection Criteria for Dialysis and Renal Transplant

BY STANLEY RABINOWITZ, PH.D., AND HERMANUS I.J. VAN DER SPUY, PH.D.

In a number of countries there are limited dialysis and transplantation facilities, and not all patients can be selected for renal treatment. Those who must make the selection are burdened with the moral dilemma of deciding who is to live and who is to be left to die. With no clearly established medical, social, psychiatric, or psychological criteria for selection, the decision is difficult and must inevitably include the subjective impressions of the selection team.

Researchers (1–3) have indicated that patients with end-stage kidney disease face three broad areas of stress. Physically, they face the stress of physiological changes and discomfort, including adherence to a strict diet and restrictions in fluid intake. Psychologically, they face the stress of increased dependency on the dialysis machine and the renal team. Socially and personally, they face increased financial and emotional dependency, frustration of their instinctual drives, and various associated limitations.

There is no general agreement on the factors determining favorable adjustment to dialysis. While earlier investigators (4, 5) suggested that average or above average intelligence was an important prerequisite for favorable dialysis adjustment, recent in

gram was made by a team that consisted of surgeons, a psychiatrist, other physicians, a clinical psychologist (S.R.), and a social worker. Other than identifying them as an upper-middle-class group of professionals, no more detailed investigation of their religious or political beliefs or their psychological characteristics was undertaken. Because of the sensitive nature of the study, such investigations were not regarded as feasible.

Psychological measures and procedure. The groups, which were controlled for age, sex, and race, were contrasted on the following psychosocial measures: the Wechsler Bellevue Adult Intelligence Scale (verbal subtests), Standard Progressive Matrices, Rorschach Inkblot Test, and social class and education. Performance IQ subtests could not be administered because some of the patients were bedridden. However, the Standard Progressive Matrices, often regarded as a measure of general intellectual ability (8), served as the measure of general intellectual level of functioning. The Progressive Matrices percentile scores were converted to IQ equivalents according to the conversion table of Peck (9).

Social class levels were rated according to the scoring system developed by the Child Guidance Clinic of the University of Cape Town. Scores were assigned on a range of 1–6 in ascending order for each class division so that persons falling in class 6 (unskilled workers) obtained a score of 6, persons falling in Class 5 (semiskilled workers) obtained a score of 5, and so on. Education was scored on the basis of one point for each year. The Rorschach was scored according to the quantitative proportions of Klopfer, and the following personality dimensions were studied: 1) inner resources and impulse life; 2) affectional needs, 3) control factors, 4) emotional reactivity to the environment, and 5) intellectual manner of approach. The researchers also used the Rorschach scoring system developed by van der Spuy (10).

Results

Significant differences were found between the accepted and rejected groups on three measures (see table 1). The accepted sample had a significantly higher verbal IQ than the rejected group. Analysis of the subscales revealed significantly higher scores by the accepted sample on all the subtests except digit span. Both social class and education were significantly higher for the accepted than for the rejected group.

No significant differences between the groups on any of the personality variables were revealed by the results of the Rorschach.

Although there was a 5-point difference in favor of the selected group based on the Progressive Matrices IQ score, this is not statistically significant, whereas the selected group scored more than 20 points higher on the Wechsler verbal IQ. Verbal intellectual functioning is much more affected by cultural factors than a performance scale like the Progressive Matrices. The results would suggest that social and educational background emphasized and magnified any differences in intellectual potential that might have existed in the two groups.

TABLE 1
Comparison of Patients Accepted and Rejected for a Renal Program

	Accepted Group (N=17)		Rejected Group (N=11)*		Analysis	
Variable	Mean	SD	Mean	SD	t	p
Wechsler verbal IQ	95.87	19.89	74.6	22.59	2.51	<.02
Progressive matrices IQ	87.75	11.85	82.81	9.09	1.16	n.s.
Social class	4.00	1.27	5.09	1.13	−2.3	<.05
Educational level (years)	8.4	2.85	5.00	3.31	2.9	<.01

*One of the accepted patients and 1 of the rejected patients would not cooperate and failed to complete the WAIS. One of the accepted patients could not adequately complete the Standard Progressive Matrices because of poor eyesight.

Discussion

The results of the present study support the hypothesis that those patients with whom the selection team can more readily identify are more likely to be accepted for the renal program. The accepted sample showed significantly higher scores than the rejected group on measures of verbal intelligence, social class, and educational levels, while no significant differences were found between the groups on measures of general intellectual level of functioning and on personality variables.

These results seem to suggest that selection for the program was probably based on clearly perceivable but superficial characteristics such as verbal intelligence, social class, and education. The assumption is that the upper-middle-class professional selection team can identify more readily with these characteristics. In the absence of clear-cut criteria for selection, the team was probably influenced primarily by these superficial variables. However disturbing these findings might be, they do not imply condemnation of the selection team. In the absence of clear-cut selection criteria, many people would probably use similar subjective criteria without being aware they were doing so. Similar subjective and perhaps subconscious criteria probably operate in a wide range of selection situations, e.g., employment or medical school admission.

Despite the many difficulties and problems associated with the development of objective criteria for selection, we believe that research should be undertaken in order to establish more exact criteria. Until this is done, we are convinced that selection for treatment will continue to be made on the superficial variables we have outlined.

Successful Treatment of Severe Anxiety Attacks with Tricyclic Antidepressants: A Potential Mechanism of Action

BY KENNETH JOBSON, M.D., MARKKU LINNOILA, M.D., PH.D., JOHN GILLAM, M.D., AND JOHN L. SULLIVAN, M.D.

A correlation between plasma tricyclic antidepressant levels and treatment responses has been demonstrated in moderate to severe depressions (1, 2). A curvilinear relationship has been reported for the secondary amines (1), whereas a linear relationship has been observed for the tertiary amines (2). The doses necessary to reach therapeutic levels have generally varied between 2 and 4 mg/kg of body weight, depending on which drug has been administered to which patient (1, 2). Low-dose tricyclic treatment (doses below 1 mg/kg) has been reported to be effective in the treatment of severe paroxysmal phobic anxiety (3).

Using gas chromatography we measured the plasma tricyclic levels during steady state kinetics in three severely anxious patients. All three patients had suffered from severe panic attacks, agoraphobia, and somatic anxiety symptoms for more than a year before the study. The symptoms had been disabling and were not alleviated by standard therapeutic doses of benzodiazepine medication. Low doses of tricyclic antidepressants induced a dramatic resolution of symptoms in these patients. When the patients stopped their medication all symptoms returned to their previous level of severity, and when the medication was r symptoms again disappeared. Plasma t during the initial management period ar table 1.

This dramatic resolution of severe an three patients with plasma tricyclic le low those reported for successful mana vere depressions makes it reasonable t mechanism of action for the tricyclics i of anxiety attacks that differs from the cepted mechanism in the treatment Drugs other than tricyclics reported to the treatment of severe anxiety attack monoamine oxidase inhibitors and prop All three classes of drugs can block β- ceptors (6, 7). We have found MAO in the most clinically effective agents in t severe anxiety attacks and propranol fective. Propranolol is the most pure blocker of these drugs, so we do not sug of central beta receptors as the mechan action in the treatment of severe anxiety tral adrenergic alpha-receptor blockade able in the treatment of anxiety (8), bu pha-receptor blockade after tricyclic a in man has been suggested to occur at higher than those necessary in the treatm sion (6). Therefore, adrenergic alpha-re ade is an unlikely mechanism of actio cyclics in treating severe anxiety attack

Both MAO inhibitors and tricyclic a have been reported to inhibit MAO in h in vivo (9). In addition, the degree of M

When this work was done, Dr. Jobson was Chief Resident of Clinical Psychopharmacology and Psychiatry Resident, University of North Carolina, Chapel Hill, N.C.; he is now in private practice as Co-Director, Tennessee Psychiatry and Psychopharmacology Clinic, 9401 Parkwest Blvd., Knoxville, Tenn. 37919, and Clinical Assistant Professor of Psychiatry, University of Tennessee. TABLE 1
Three Patients Treated with Tricyclics for Severe Anxiety

Patient Number	Sex	Drug	Dose (mg/day)	Plasma Level (ng/ml)
1	Male	Imipramine	25	Imipramine, 50 Desipramine, >5<10
2	Male	Imipramine	25	Imipramine, 10 Desipramine, >5<10
3	Male	Amitriptyline	25	Amitriptyline, >5<10 Nortriptyline, >5<10

in human platelets seen after tricyclic administration is generally lower than that seen after MAO inhibitors (9). This is the same order of potency that we have seen in the treatment of anxiety attacks. Since in vivo MAO inhibition in human platelets can occur at very low tricyclic plasma levels and has been reported to correlate with the sedative effects of the tricyclics (9), MAO inhibition may be the mechanism that mediates the management of severe anxiety attacks.

Abnormal Gaits in Tardive Dyskinesia

SIR: Tardive dyskinesia continues to present problems of both a practical and theoretical nature. The continuing attention this problem has received has resulted in a broadening of the definition of the syndrome and a further awareness of its complexity and importance. We would like to bring attention to the presence of abnormal gaits in patients suffering from severe tardive dyskinesia. The gaits were noted as patients walked about the wards and hospital grounds. When further examined, the patients showed other signs of dyskinesias (e.g., buccolingual masticatory movements and choreoathetoid movements of the limbs). Abnormalities of posture have been reported previously (1), but we are not aware of any detailed descriptions or any comments about its frequency.

We examined 42 patients selected as having at least moderate symptoms of tardive dyskinesia (e.g., oral abnormalities and choreoathetoid movements of the limbs). Of these 42 patients, 18 (43%) had "peculiar" gaits. The gaits of 9 (22%) were considered frankly abnormal, i.e., neurological gaits, characterized as follows:

1. Broad-based gait, i.e., a wide gait with a wide arm swing and an unsteady gait. Of the 7 patients in this category, 3 had pelvic thrusting (forward movements of the pelvis on walking), and 2 walked predominantly on their heels, giving the appearance of a steppage gait.
2. What appeared to be a spastic gait, with the dragging of one foot, was seen in 2 patients.

The remaining 9 patients had what seemed to be an abnormal gait, but it was not typical of any described neurological gait.

More detailed descriptions of the gaits included unsteady, wide-based gait; marked swinging of arms; broad-based, unsteady, pelvic thrusts similar to a pregnancy strut; walking on heels; deliberate, careful wide steps; broad-based, unsteady walking on heels; stiff, unsteady gait, dragging feet; stamping type gait; and so forth. In some patients there was a cerebellar quality, while others had wide arm swing movements reminiscent of ballistic movements. A neurologist who saw 1 patient for evaluation described the patient as having "dystonic movements of the facial muscles together with occasional grunting but without rigidity of the muscles of the trunk or extremities with a mildly abnormal gait. The patient preambulated with a protrusion of the upper chest muscles and a somewhat steppage gait. The reflexes are normal and it would seem that these choreiform and dystonic movements are a result of tranquilizing drugs, i.e., tardive dyskinesia."

It should be emphasized that these observations come from a highly selected group of patients, and ... to the attention of *Journal* readers as further ... complexity of tardive dyskinesia and also as ... in the diagnosis of this condition, although ... should, of course, be made long before t... progressed to this stage.

Work Stress

SIR: For the last two years we have be... number of seminars and workshops for gov... and private employees experiencing wo... have included such people as nursing ex... managers, and rank-and-file employees. I... not required to have problems, and many ... the workshops with an intent to learn som... than to seek remedial measures.

We have observed in surveys of the partic... two-thirds of work stresses stem from ot... lems. Another third report stresses that ar... sures. It would thus be useful for the he... understand sources of and coping techniq... of pressure. We found that work stresses o... at one time or another, even among partici... identified problems. We were chagrined to ... health professionals frequently were not a... to counsel people experiencing work stress... of their lack of managerial perspectives ... indicate that mental health centers are p... most other organizations in terms of the ... tensity of work stresses, and that the men... sionals themselves are often unable to cop... job stresses.

We found a number of realizations to be ... people experiencing stress at work. First is ... fact that political relationships are inherent ... tion. One must understand that power, in ... thority exist in any organization. A second ...

the notion of coping with stress using only "fight or flight" reactions is insufficient. "Fight or flight" is more appropriate to the lower animals; man is more able to "fight, flight, or take things in stride." A third realization we found helpful is the need for individuals to be willing to listen to others experiencing work stresses in the same organization. Perhaps this is consistent with the systems viewpoint, which sees stresses as cumulative and interactive. When one lowers the total amount of stresses in an organization, one is helping oneself as well. Fourth is respect for one's coworkers, even when liking others has become difficult if not impossible, or when there is a need to discipline, criticize, or disagree.

An interesting observation occurred with respect to the so-called burning-out syndrome, which seems to be almost ubiquitous, with varying intensities and reactions. The people who report being burned-out generally were describing a phenomenon of partial disengagement from their work, loss of motivation, winding down, and turning off which is probably related to a form of taking psychological flight without physical escape from the interaction.

On Assessing Violence and Dangerousness in Mental Patients

SIR: In "Crime and Violence Among Mental Patients Reconsidered in View of the New Legal Relationship Between the State and the Mentally Ill" (January 1978 issue), Larry Sosowsky, M.P.P., implied that former San Mateo County Mental Health Division patients are an extraordinary danger to the community because they have a higher incidence of arrest records for criminal behavior, including violent offenses, than the general population. He also implied that this study took place with the approval and assistance of the San Mateo Mental Health Services Division. Neither implication is correct.

Mr. Sosowsky's implied conclusion that San Mateo County patients released from Napa State Hospital subsequently committed violent crimes at a higher rate than the general population is invalid. Although a certain percentage of the patients had arrest records, no data are provided indicating the number of actual convictions, which could be the only acceptable basis for characterizing people as "violent offenders."

The majority of the arrests may well have occurred before the pivotal hospitalization, not after discharge (see p. 35 of the article, indicating a 19-month study period from June 1972 through December 1973).

The broader aspects of this report deal with arrests from January 1966 through March 1974, so that $6\frac{1}{2}$ years of the $8\frac{1}{4}$-year survey period fall before the pivotal hospitalization. The more focused aspects of the report, dealing with rates of violent crime during the "postreform" period (p. 38), counted arrests for a $4\frac{3}{4}$ year period (July 1969–March 1974), 3 years of which were before pivotal hospitalization. Indeed, 28 of the 301 survey individuals had not been discharged as of January 1, 1974 (p. 37).

What the author's data do show is that before pivotal hospitalization this survey group of state hospital admissions had a higher rate of arrests for violent offenses than their counterparts (in terms of age, sex, and race) in the general San Mateo County population, assuming the author's method of estimating those rates is correct.

It is little wonder that high arrest rates are associated with being admitted to Napa State Hospital, since some of these admissions came directly through the criminal justice system. This would include those who experienced a psychotic break while in jail, those who entered "insanity" pleas for their alleged crimes, etc. The author apparently did not segregate the data of these "penal code" cases, and they are not analyzed separately, as good research procedure would require. We estimate that approximately 12% of San Mateo's Napa State Hospital caseload during this pivotal hospitalization period were such penal code cases. Including this group clearly adds bias to Mr. Sosowsky's report.

The procedure for calculating the annual arrest rate figures for San Mateo County and several U.S. cities is not clearly described by the author and backup data are not provided. Without these data, no independent assessment of the rates he used is possible.

This article has received wide notice, was picked up by the Associated Press, and has already been cited in an editorial (1) opposing proposed amendments to the Mental Health Act of one state legislature—amendments which would tighten criteria for involuntary admission to state hospitals. The editorial cited the study's findings to the effect that the crime rate of former mental health patients has increased by a factor of three and a half since passage of California's 1969 legislation limiting the duration of involuntary hospitalization. Thus, the article is being used to perpetuate the stereotype of all mentally ill as criminally dangerous and violent persons, which they are not.

1. Mental health trends boost crime rate (editorial). Tallahassee Democrat, Jan 28, 1978, p 4A

ROBERT M. RANKIN, M.D., M.P.H.
GARY M. HEYMANN, PH.D.
San Mateo, Calif.

SIR: The data on the dangerousness of the mentally ill presented by Mr. Sosowsky in the January 1978 issue of the *Journal* have important implications for public policy. Specifically, Mr. Sosowsky appears to agree that California commitment and release policies may have become too liberal to effectively protect the public from dangerous mental patients.

It behooves us to take a careful look at this research to ensure that hospitalized patients are as dangerous as the data suggest. In our view there are problems with this research that render its interpretation extremely hazardous.

Mr. Sosowsky examined the arrest rates of persons who are admitted to Napa State Hospital from San Mateo's community mental health program. This group is highly select in that a decision has been made that they are inappropriate for outpatient treatment because they are deemed dangerous to themselves or others. The criteria for assessing dangerousness no doubt include previous criminal history, and the reason for referral was probably an arrest for a criminal offence in many cases.

In view of these considerations, the only conclusion possible is that the admission screening process is working, as it should, to identify truly dangerous persons. Certainly, no inference can be drawn regarding the dangerousness of mental patients from this highly selected group. In fact, the data that Mr. Sosowsky has gathered do not even address the issue he raised in his discussion section regarding the societal costs of

current admission and discharge policies because the crimes of the patients he studied were all committed before their hospitalization.

VERNON L. QUINSEY, PH.D.
MANFRED PRUESSE, PH.D.
Penetanguishene, Ont., Canada

Mr. Sosowsky Replies

SIR: Drs. Rankin and Heymann's comments perplex me. They assert my "implied conclusion that San Mateo County patients released from Napa State Hospital subsequently committed violent crimes at a higher rate than the general population is invalid," offer points to buttress their assertion, note the wide audience my article has received, and then conclude that my article is being used to "perpetuate the stereotype of all mentally ill as criminally dangerous . . . which they are not."

Nowhere in my paper did I indicate I intended to analyze postdischarge arrest activity. At the outset I made it clear that my "report presents the results of [an] earlier one so as to match closely the methods used by Zitrin and associates." I reported findings which confirmed those of Zitrin and associates, suggested an explanatory hypothesis, and offered what continues to strike me as the appropriate warning. For Drs. Rankin and Heymann to declare my "implied conclusion" invalid without meeting squarely the conclusions I stated explicitly seems to me an effort to shift attention away from what I actually said. Certainly they can acquire the unpublished "back-up data" I relied upon, using the references in my paper, in order to conduct that type of independent assessment if they feel it is called for. In 1974 my earlier report was received by a statewide audience and also picked up by the Associated Press. Regardless, since I did not report my data in a manner that addressed the particular dimension of postdischarge arrest activity, no conclusion on this issue, valid or invalid, can yet be drawn from my published findings. I want to add here that I decided to set up table 5 in my paper to reveal prereform/postreform arrest activity rather than preadmission/postdischarge activity in part because my arrest data included only arrests occurring within 3 months of the last admission and, more importantly, in view of the hypothesis I had in mind this type of partition was crucial. Frankly, I now regret that I did not add the additional table with the postdischarge arrest activity I did analyze, although I continue to think this dimension is not essential to my preliminary paper.

Drs. Rankin and Heymann's other points do not seem to support their own assertion. For instance, they claim convictions "could be the only acceptable basis for characterizing people as violent offenders." There is not unanimity on this issue. I relied on arrests because I concur with Zitrin and associates' judgment that records of conviction are a less accurate index of criminal behavior because many offenders are found incompetent to stand trial or are taken out of the court system before that stage of the legal process takes place (1, 2). A recently released report by the New York State Department of Mental Hygiene on the insanity defense seems at first blush to provide empirical substantiation for this judgment: the use of the defense for acquittal in New York rose fourfold to 225 in the period of 1971 to 1976, up from 53 in the period of 1965 to 1971 (3). This increase occurred after the civil commitment law in New York was liberalized. I do intend, and I stated this in my paper, to analyze and report conviction rates—not beca[illegible] much fundamental insight will be added but [illegible] completeness requires it.

One criticism Drs. Rankin and Heymann[illegible] mental. Their observation seems to reflect [illegible] most observers trying to explain the high cri[illegible] ed in current studies (1, 4, 5). My asserted [illegible] this criticism, according to Drs. Quinsey and[illegible] ders interpretation of my data "extremely ha[illegible] observation is that the high crime rates repo[illegible] ably be explained to some extent by the increa[illegible] of arrested persons from the criminal justice [illegible] tal hospitals. This criticism is connected to [illegible] aspect of this entire matter—the current stri[illegible] criteria. The consequence of both of these as[illegible] samples against which current studies calcul[illegible] violence contain a larger proportion of arreste[illegible] was found in the past. It was precisely this [illegible] with the elaboration that many of the individu[illegible] ly considered nondangerous mentally ill are [illegible] from the state hospitals, that the final reviewe[illegible] used in admonishing me to demonstrate that [illegible] did not simply reflect the demographic ch[illegible] stringent admission criteria. Apparently, I fa[illegible] level of doubt to satisfy the final reviewer [illegible] None of the authors of the two letters acknow[illegible] ness of my paragraphs addressing the contr[illegible] diversion and the changes in current admiss[illegible] my theoretical control for these factors. Th[illegible] curious in the case of the letter by Drs. Quins[illegible] since they acknowledge the obligation to [illegible] look" at my research before they assert [illegible] clusion possible is that the admission screen[illegible] working . . . to identify truly dangerous p[illegible] "more liberty—more criminal activity" seem[illegible] sible explanation for some of the increase in[illegible] ty. The critical question remains for me, how[illegible]

I am aware that what economists chara[illegible] reto-optimal solution may be beyond our rea[illegible] the task which I think is presented by the ne[illegible] ship between the state and the mentally ill. [illegible] value absolutely bringing this existential c[illegible] sharp a focus as the scientific method will a[illegible]

Sodium Seconal and Methadrine for Mute Pa[illegible]

SIR: In their article "Sodium Amylobarb[illegible] ferential Diagnosis of Confusion" (January [illegible]

Nicholas G. Ward, M.D., and associates described a diagnostic technique that seems to have fallen into disuse since its popularity during World War II. I learned a similar technique from an older psychiatrist (Dr. Reynold Flom) who had been in World War II and later in the Korean War. There was a slight modification in technique: sodium seconal was used instead of sodium amylobarbitone, and 20 mg of methadrine was added. I have had fairly good results in using this approach with mute patients where the diagnosis was in doubt after the patient had been carefully examined to rule out organic etiology. The following are three case examples.

A 17-year-old high school student had suddenly become mute at home. After 3 days' hospitalization he refused to speak, although he cooperated with hospital routine. Associated signs and symptoms included insomnia, restless sleep, rigid posture, and staring off into space. There was no family history of psychiatric disorder. Following the injection of 250 mg of sodium seconal and 20 mg of methadrine, the patient began to speak and answer questions. Florid delusional material was obtained, and a mental status exam supported the diagnosis of functional psychosis. Within a few days after beginning phenothiazine medication, the patient began to speak. He made an uneventful recovery over the next several weeks and was able to return to his class at high school.

A 39-year-old evangelical clergyman visiting the Twin Cities from his home in Canada suddenly became mute, immobile, and unresponsive during a church service. The parish leaders brought him to the hospital for psychiatric care after praying over him for approximately 24 hours. History revealed that he had had a few "breakdowns" treated by his community general practitioner in Canada. During the first 24 hours of hospitalization, he did not respond to questions and refused all food and fluid. He became severely dehydrated, so intravenous fluids were started. After administration of 300 mg of sodium seconal and 20 mg of methadrine, he verbalized paranoid delusional material as well as auditory and visual hallucinations. He responded to treatment with phenothiazines and was able to return to Canada in two weeks.

A 24-year-old disheveled woman was brought to the hospital by police who had found her confusedly wandering the streets of the city at night. She was mute and refused to communicate in any fashion. Physical and laboratory evaluation were entirely normal. When further information could not be obtained after she had been in the hospital for 48 hours, 200 mg of sodium seconal and 20 mg of methadrine were administered. However, despite the medication, she remained mute. About 3 days later, the police were able to ascertain her identity from friends with whom she lived. She was a heavy user of many different drugs and had had several previous psychiatric admissions for psychosis. She did not respond to brief hospitalization and phenothiazine medication and was transferred to a state psychiatric hospital for more extended care.

These few cases indicate that the method can be extremely useful for diagnosis but is not inevitably successful. The methadrine can induce tachycardia and extrasystoles, so it probably should not be used in those with a history of cardiovascular disease. The advantage of the longer-acting sodium seconal is that interviews may be continued over an hour or two in responsive patients. As noted by the authors, slow injection is necessary to avoid overdose or laryngeal spasm. Resuscitation equipment should be at hand.

Defining "Schizophreniform Psychoses"

SIR: I have received letters concerning the dichotomy of the broad term "schizophrenia" in typical (process) schizophrenias and schizophreniform psychoses, which I proposed in 1937 (1). I think it may be of interest to emphasize that the schizophreniform psychoses are not a collection of special types of psychoses. Only psychoses characterized by very typical initial symptoms should be diagnosed as "schizophrenias." If these symptoms are not present but the patient has, among other symptoms, hallucinations and/or delusions, the diagnosis should be schizophreniform psychosis. It was found in the International Pilot Study of Schizophrenia that in 9 countries the symptoms of "schizophrenia" corresponded so well that it is now possible to work with a transcultural symptomatology. It is of the greatest significance in research, diagnosis, and therapy of schizophrenia that all researchers use these symptom criteria when diagnosing "schizophrenia"; cases similar to this diagnosis are termed schizophreniform psychoses. In Scandinavia these psychoses are now considered as special types of reactive psychoses similar to schizophrenia.

I hope this information may be of help to researchers in this area.

"HMC" Treatment Recalled

SIR: "Methadone in Schizophrenic Rage: A Case Study" (February 1978 issue) by Gilbert H. Berken, M.D., and associates documents the use of methadone maintenance in a case of schizophrenic rage. It might be of interest to recall that narcotic drugs were used for acute schizophrenic or manic patients in rage before the appearance of barbiturates and phenothiazines. Around the time I began medical practice in the early 1960s, an older psychiatrist taught me the use of an old nostrum, HMC (hyoscine, morphine, and cacalyptus). It was available in two doses, one with a half grain and the other with a quarter grain. One dosage was all that was ordinarily required when phenothiazine medication was started at the same time; in rare instances HMC was continued for a day or two. It had the advantage of calming acutely disturbed patients without inducing the severe extrapyramidal side effects so commonly seen with high doses of phenothiazine and similar antipsychotic medications. In the narcotophobic era of the later 1960s and early 1970s, this useful treatment modality apparently fell out of favor. Now

that we are in a more dispassionate period, it might be time to reconsider judicious use of this treatment.

JOSEPH WESTERMEYER, M.D.
Minneapolis, Minn.

Phenothiazines and Night Terrors

SIR: In their report "Pavor Nocturnus in a Schizophrenic Patient: A Review and Case Study" (February 1978 issue), Malcolm N. McLeod, M.D., and Paula Fisher, M.D., reported that phenothiazines were successful in controlling the patient's chronic schizophrenic symptoms but did not control his night terrors, while diazepam, 15 mg h.s., provided excellent control of this very disturbing problem. I wish to point out that these observations were predictable in light of recent findings in sleep research. Since it is known that phenothiazines tend to increase stage 4 sleep, one should not expect them to alleviate pavor nocturnus, which is associated with stage 4 sleep. In fact, phenothiazines might well produce or exacerbate this problem, particularly when given in a single daily bedtime dose (1). Benzodiazepines are known to suppress stage 4 sleep (2) and have been shown to be effective in controlling pavor nocturnus (3). When one also considers their margin of safety, benzodiazepines should be the drugs of first choice in treating pavor nocturnus.

WILFRID L. PILETTE, M.D.
Worcester, Mass.

Drs. McLeod and Fisher Reply

SIR: We agree with Dr. Pilette that phenothiazines may exacerbate pavor nocturnus. Further, we did not expect chlorpromazine to control the patient's pavor nocturnus; we simply reported that these drugs did not control the night terrors. Indeed, we felt that the pavor nocturnus attacks were exacerbated by increasing doses of chlorpromazine, but this evidence was not strong enough to report. Our patient was treated several years ago, long before the report that single doses of a tricyclic or neuroleptic exacerbate pavor nocturnus (1). Thus, our observations were not as "predictable" as Dr. Pilette suggests.

False Positives in the Differential Diagnosis of [illegible] Amytal

SIR: I read with interest the recent article by [illegible] Ward, M.D., and associates, "Sodium Amy[illegible] the Differential Diagnosis of Confusion" [illegible] issue). Their conclusion that confusion wh[illegible] the use of sodium amylobarbitone probably [illegible] etiology is in agreement with my clinical exp[illegible]

However, there is one major source of pote[illegible] tives (i.e., organic confusion clearing under [illegible] dium amylobarbitone) that was not mentioned [illegible] and may be a significant source of diagnost[illegible] the normalizing effect that hypnotics may h[illegible] dysrhythmias. Detre and Jarecki (1) discusse[illegible] hypnotics may have a normalizing effect on [illegible] (1). A patient whose confusion is caused by [illegible] cerebral dysfunction may improve rather th[illegible] when given a hypnotic. Unless this is recog[illegible] mistake such a clearing as evidence of a funct[illegible] and not recognize that the hypnotic has serve[illegible] improve the organic condition (dysrhythmi[illegible] possibility exists that one of the cases des[illegible] thors as functional confusion may have been j[illegible] positive.

Their second case report described a 36-ye[illegible] a history of grand mal and petit mal epilepsy [illegible] with bizarre, agitated behavior, loose associ[illegible] ideation, and disorientation to place. Upon re[illegible] of sodium amylobarbitone I.V. the patient's [illegible] noted to clear, and he was then treated with [illegible] 30 mg of phenobarbital t.i.d. Although the au[illegible] that this represented a schizophrenic illnes[illegible] tion described also seems quite compatible [illegible] ictal psychosis which responded to the antic[illegible] erties of the intravenous barbiturate.

Dr. Ward and associates stated that "Psych[illegible] to epilepsy was ruled out, because psychosis [illegible] has been reported only in psychomotor epile[illegible] cases 'there is never a continuous spike and [illegible] as was seen in this patient." Wells and as[illegible] scribed two cases of transient ictal psychos[illegible] others from the literature which show that suc[illegible] present a varied clinical picture that can mi[illegible] hysterical, and schizophrenic psychosis as w[illegible] These were associated with continuous or ne[illegible] petit mal variant discharges.

If this patient did exhibit a continuous spik[illegible] charge, this would be characteristic of stat[illegible] amytal is described in the dosage used by t[illegible] treatment for status epilepticus (3). Therefo[illegible] initial improvement could be attributed to cer[illegible] zure activity and his continued improvemen[illegible] sulted from the anticonvulsant effects of th[illegible] rather than the thiothixene. His history of [illegible] izations may represent previous episodes of [illegible] that had also gone unrecognized.

Whether this is actually the case or not, the [illegible] positive is an important point that should [illegible] when using intravenous hypnotics for such [illegible] poses.

STEWART SHEVITZ, M.D.
Nashville, Tenn.

Dr. Ward and Associates Reply

SIR: Dr. Shevitz's point is well taken. Transient ictal psychosis may be a source of false positives with the amytal test. Past and present improvements in the second patient we described have appeared to correlate better with the institution of antipsychotic medication than with the development of therapeutically effective barbiturate levels. However, this is only a clinical observation, and the possibility of status epilepticus in that patient still exists.

We have also considered the possibility of limbic system seizures as reported by Monroe (1) as a source of false positives. Such seizures may not give abnormal EEGs under normal testing but may still respond to intravenous amytal.

Diagnostic Guidelines for Demented Patients

SIR: In his article "Chronic Brain Disease: An Overview" (January 1978 issue) Charles E. Wells, M.D., suggested guidelines for the evaluation of the demented patient before or instead of neurological consultation; these suggestions are welcome but deserve comment. Dr. Wells recommended a CT scan as a screening procedure in his basic diagnostic battery and does not suggest examination of the cerebrospinal fluid (CSF). There seem to be both diagnostic and logistic considerations in this regard.

There are some diagnoses that can be made by CT scan even with a negative CSF exam (e.g., normal pressure hydrocephalus), but there are others in which the CSF will give positive findings with a negative CT scan (e.g., CNS infection, early metastatic disease, multiple sclerosis). In two series quoted, Marsden and Harrison (1) and Freemon (2) both examined CSF as part of their protocols. In the former study, 1 out of 36 cases of identifiable causes of dementia was obtained by CSF exam, and in the latter, 2 out of 60. Additionally, Marsden and Harrison found no vitamin B_{12} deficiency, and Freemon concluded, "Unrewarding tests included . . . vitamin B_{12} and folate levels."

The CT scan is not readily available in all areas of the country, and its cost, while decreasing in high-availability areas, must remain a consideration for some patients. Similarly, the facilities to do a lumbar puncture may not exist in many psychiatrists' offices, although enlistment of hospital outpatient facilities (as well as house staff) may be a partial solution.

It would thus be of interest to learn the reasons for Dr. Wells' exclusion of CSF examination in his suggestions, as well as his inclusion of B_{12} and folate levels.

ALAN F. JAVEL, M.D.
Martinez, Calif.

Dr. Wells Replies

SIR: I am grateful to Dr. Javel for his comments and for the opportunity to explain more fully the reasons for my suggestions.

The most important reason why I did not and do not advise *routine* lumbar puncture for demented patients is its low yield of specifically useful information. I did not mean to suggest that I never use this diagnostic procedure or that it is not on occasion very useful, but I reserve its use for those patients whose history or clinical findings suggest that examination of the CSF may be of specific diagnostic or therapeutic value. In only 1 patient (with syphilis) out of 166 in the two series mentioned by Dr. Javel did CSF findings provide an exact diagnosis. As Dr. Freemon reported, this patient had a positive serum VDRL and an Argyll Robertson pupil, either of which would have made examination of the CSF mandatory in that patient. As Dr. Javel notes, CSF examination provides exact diagnostic information only in CSF infections, early metastatic disease, and multiple sclerosis. These disorders rarely present as dementing syndromes per se, and even more rarely without other clinical features pointing to the correct diagnosis.

Even though the diagnostic yield is low with lumbar puncture in dementia, I would probably accept its routine use were the procedure noninvasive, inexpensive, and attended by no significant morbidity. It is indeed for these reasons that I have suggested determination of B_{12} and folate levels routinely in dementia even though the yield is low. However, lumbar puncture does not meet these criteria. It is invasive, expensive (in terms of time and equipment) for both physician and patient, and attended by considerable morbidity (the pain of the procedure itself and the posttap headache).

I realize that some believe the omission of the routine CSF examination is unjustified. I am ready to change my recommendations if good evidence for such routine use is forthcoming. However, studies to date do not, in my opinion, support this position.

Nashville, Tenn.

Depression in Chronic Schizophrenia

SIR: We read with interest "The Assessment of Depression: A Model for Quality Review of Emergency Psychiatry" by Frederic Kass, M.D., and associates (February 1978 issue). The results of this study come as no surprise to us.

In 1975 we conducted a similar study at West Valley Mental Health Clinic, an affiliate of the UCLA School of Medicine. In our study, 96 schizophrenic outpatients with clinically diagnosed "flattened" affect were psychometrically tested using the Zung Self-Rating Depression Scale (SDS) to determine specifically whether a latent underlying depression existed in a significant number of these patients. These selected patients had denied feelings of depression and did not appear to us to be depressed. The SDS was administered to each patient. Test results clearly indicated that all subjects were experiencing moderate to severe depression. Specifically, scores for the 96 patients ranged from 54–88, with a mean of 67 (SD=13.44).

Now that the existence of depression in chronic schizophrenia has "come out of the closet" we would hope that clinicians will take this into account in the diagnosis and treatment of the affect as well as the thought disorder. This should improve the overall functioning of schizophrenic patients.

Reprint requests or additional information concerning our study should be directed to us at the address below.

Differential Diagnosis in Recognizing Alcoholism

SIR: We would like to share with your readers an incident at our hospital which points up the need for extreme care in differential diagnosis. Recently, five patients diagnosed as psychotic were admitted to our acute care psychiatric unit. Each patient was prescribed a major tranquilizer. One typical case report follows:

> A 52-year-old woman was admitted and diagnosed as a gravely disabled paranoid schizophrenic and placed on haloperidol, 5 mg t.i.d. On later questioning by a team consisting of a psychiatrist, a psychologist, a clinical pharmacist, and a social worker, she initially denied all but occasional use of alcohol. After more intense questioning, she admitted to very heavy drinking and three convictions for driving while intoxicated, one of which involved an accident in which she received a head injury. At this point all neuroleptic drugs were discontinued. The patient was placed on chlordiazepoxide, 10 mg t.i.d. and 25 mg h.s.; thiamine, 100 mg/day; and flurazepam, 30 mg h.s. Laboratory values were normal except for total protein 5.5 (normal=6.0–8.3) and globulin 1.9 (normal=2.0–3.5). The patient's mental condition greatly improved and she was discharged to continue her therapy on an outpatient basis shortly thereafter.

Great care should be taken in the differential diagnosis of alcoholism and schizophrenia at the time of admission because there is substantial evidence that the major tranquilizers used in the treatment of psychoses can lower the seizure threshold during alcohol withdrawal and thus possibly precipitate a grand mal seizure (1). Before one prescribes a major tranquilizer for a newly admitted patient, a procedure of very thorough questioning, evaluation, and history taking should be exercised during the initial interview to rule out the possibility of alcoholism.

NEAL R. CUTLER, M.D.
JON F. HEISER, M.D.
Orange, Calif.

Dr. Moore Replies

SIR: I would like to respond to some of Drs. Cutler and Heiser's inquiries and concerns. I do agree with them that suppression of symptoms may forestall diagnostic measures and, in fact, stated in my paper that "Optimum management of delirium includes diagnosis and treatment of the underlying cause of the cerebral insufficiency and symptomatic treatment of the delirium itself." Space limitations precluded a full description of the diagnostic measures taken in this case, which included complete physical examination, detailed history with regard to prior drug use, urinalysis, complete blood count, SMA-18, prothrombin time, arterial blood gases, chest X-ray, ECG; EEG, lumbar puncture, and cultures of urine, sputum, and blood. None of the measures proved enlightening. The patient's systemic medications included only morphine and diazepam, the dosages of which had been unchanged for the 4 days before the onset of the delirium. Thus the only diagnosis I could make was delirium of unknown etiology.

Drs. Cutler and Heiser's point regarding the danger of treating delirium secondary to anticholinergics or to antipsychotics with haloperidol is well taken, and I did not mean to imply that it should be used in these conditions. However, I can think of few other conditions, with the possible exception of withdrawal syndromes, in which it would be dangerous to use haloperidol. As I noted in my paper, "Controlled studies are needed."

My own concern with the tone of their letter is that it might lead some physicians to withhold drug treatment in a critical situation until all diagnostic studies were done. A full diagnostic workup must be done on all delirius patients, but in those who present with potentially life-threatening behavior, as was the case in the patient I described, management must be prompt and effective. Haloperidol appears, with the exceptions mentioned above, to be the drug of choice in such situations.

Pretrial Commitment

SIR: We found the recent article by Jeffrey L. Geller, M.D., and Eric D. Lister, M.D., "The Process of Criminal Commitment for Pretrial Psychiatric Examination: An Evaluation" (January 1978 issue) and the "Comment" by Alan Stone, M.D., (January 1978 issue) an intriguing and timely commentary on the process of pretrial commitment in Massachusetts. In the neighboring state of Vermont, the practices of psychiatric observation are somewhat different.

Vermont's 450,000 residents are served by one state facility at Waterbury. Unlike Worcester State Hospital, Vermont State Hospital is the only hospital in the state that accepts court-ordered referrals. Therefore, our sample is truly representative of all such referrals from the entire population of alleged offenders, apart from a small minority that are done on an outpatient basis or in correction facilities. The evaluations are done by an independent forensic consultant appointed by the hospital. These psychiatrists formulate their opinions within an initial (maximum) period of 60 days. In an attempt to highlight the use of pretrial commitment in Vermont, we will briefly describe some preliminary findings of an investigation for the 5-year period of 1972–1976.

We found that in a sizable percentage of the court referrals sent to the Vermont State Hospital, there was reason to suspect a need for hospitalization and a legitimate concern for the mental status of the client. For example, 40% of the individuals referred for pretrial commitment evaluation had previously been hospitalized for psychiatric problems. At the time of hospitalization, most of these patients had been diagnosed as psychotic. We also found that the most frequent referrals, in proportion to the base rate of crimes in the state, were for serious offenses, such as arson and crimes causing harm to individuals. Another indication of the appropriateness of the pretrial commitment procedure is, as Drs. Geller and Lister point out, the number of cases that result in commitment. In our hospital, about one-third of observations end in commitment, most because of incompetence to stand trial and some because of insanity at the time of the crime and the need for further hospital treatment. In contrast, Drs. Geller and Lister found that less than 3% of their sample of referrals ended in commitment. Finally, we found that the individuals committed under these statutes did not become "forgotten" and remain for extended periods of time in the hospital. Their average hospital stay was 260 days. Following hospital treatment, all of these individuals were given supportive aftercare planning—43% had community mental health contacts (70% with individual counselors) and 11% had vocational rehabilitation.

We found, as was suggested by Dr. Stone, that judges sometimes have differing criteria for the use of the mental health laws. For instance, there was a disproportionate number of referrals from some counties with similar types and rates of crimes. We found that there were no dramatic differences in terms of previous hospitalizations, diagnosis, or disposition between these referrals and those from other counties. Thus, the most plausible explanation for this difference is the criteria used by the local court.

Furthermore, looking at the admission rates by type of admission (voluntary, physician's emergency certificate, observation) for the state hospital over a 5-year period, we noted some supportive data for Dr. Stone's balloon theory—"If one form of confinement is reduced, then another will expand." Those counties that have the highest referral rate for observations have the lowest rate for physician's emergency certificates. In addition, when the rate of voluntary admissions declines, the emergency referral rate increases. This suggests that there is a small but significant segment of the counties' population that is in need of hospitalization and will obtain these services through one process or another.

Finally, as Dr. Stone noted, pretrial commitment is sometimes used not only by the judge or state but also by defense lawyers attempting to delay the case or to otherwise benefit their clients. We found that about 21% of the referrals to the hospital were initiated by the patient or his legal representative. In such cases, it seems difficult to argue that the state is using this mechanism to sequester deviants.

Thus we found that in the state of Vermont, pretrial com-

mitment is not used only to remove noxious offenders and sequester deviants. There seem to be three reasons for referral: 1) a legitimate concern for the mental status of the alleged offender, 2) a strategy of the defense, and 3) a means for the court to seek more appropriate dispositions for alcoholics, drug addicts, or recalcitrant offenders. No doubt there are occasional abusers, but we believe these cases call for a more informed interpretation of the existing laws, not an indictment of psychiatry or the judicial system.

BRUJ M. SARAN, M.D., PH.D.
MICHAEL KLEIN
ELLIOTT BENAY
Waterbury, Vt.

SIR: Drs. Geller and Lister in "The Process of Criminal Commitment for Pretrial Psychiatric Examination: An Evaluation" (January 1978 issue) and Dr. Stone in his "Comment" helped to bring the continuing problem of pretrial commitment into the light of professional examination. Their opinions and comment once again highlight the residual social control function of the public mental hospital, a latent function that predates the role of treatment and persists in spite of criticism. The treatment functions of these hospitals have been increasingly decentralized in general hospitals and community mental health centers. However, hospitals like Worcester State Hospital remain, and they clearly serve some important residual function to the society which maintains them.

Drs. Geller, Lister, and Stone remind us that the public mental hospital is only partly a medical institution. Pretrial commitments, like civil commitments, are made by a judge. Physicians at Worcester State Hospital do not determine whether or not these committed individuals should be patients. They do not control the admission of these people or their discharge. When the "evaluation" is complete, the "patient" remains in the hospital until called by the court. Incarceration and medical treatment are subject to a complex set of governmental regulations quite apart from medical considerations.

It is ironic that simultaneous with the preparation of Geller and Lister's report, Worcester State Hospital experienced the loss of its medical directorship. Late in 1977 the position of the medical superintendent was eliminated, and Dr. David J. Myerson resigned as superintendent of Worcester State Hospital. He relinquished the governance of the hospital to a Department of Mental Health Regional Executive Committee, headed by a nonphysician. This ended almost 150 years of medical superintendency at Worcester, a tradition begun by Samuel Woodward, first President of the Association of Medical Superintendents of American Institutions for the Insane, the forerunner of the American Psychiatric Association.

This event marked both the end of an era and a return to nonmedical authority in mental hospitals. Before the nineteenth century, hospital superintendents were nonphysicians appointed by civil or ecclesiastical authorities to govern hospitals. Physicians were employees who ministered to the medical needs of patients hospitalized for a variety of social problems. The surrender of control over commitment and the decline of medical superintendency herald a return to this role for the physician and underscore the latent social control function of the public mental hospital.

It took two "outsiders" to bring this problem to professional attention. Drs. Geller and Lister rotated to Worcester State Hospital from Beth Israel Hospital for six months. Lacking prior socialization in the latent functi[on] of the public mental hospital, they were struck by the [dis]parity between the law and actual practice.

More studies like these are required. Like [these] they make that which is latent become more r[eal] remind us of the power of unspoken social forc[es] heed them or they will recur to awaken us i[n] the night.

Therapeutic Usefulness of Ergotamine Tartrate [in Narcolepsy]

SIR: We have recently encountered 4 cases [of] and periodic somnolence in which manifest[ations of] sleep attacks, cataplexy, hypnagogic hall[ucinations] sleep paralysis were markedly improved [with] tartrate only, Cafergot (each containing 1 mg [of] tartrate and 100 mg of anhydrous caffeine), and [Cafergot] lets (each containing 0.1 mg of Bellafoline, 0.[25] mine tartrate, and 20.0 mg of phenobarbital).

Subsequent follow-up in those cases has [shown]

teresting findings on day-to-day and diurnal variations of serum serotonin concentration. This letter represents a brief preliminary report of one of those cases.

A 24-year-old man with typical signs and symptoms of narcolepsy was treated with ergotamine (3–6 mg/day as tartrate), with a remarkably gratifying clinical response in several days. The patient's serum serotonin level was 70 ng/ml at 8:00 p.m. and 98 ng/ml at 8:00 a.m. on Jan. 28, 1977, and 68 ng/ml at noon and 83 ng/ml at 4:00 p.m. the next day. These levels were noticeably lower than a mean value of 148 ± 50 ng/ml, obtained from 49 normal subjects at our clinic, and remarkably similar to changes in serum serotonin concentration usually observed following administration of tricyclic antidepressants, which are considered by many to be the drugs of first choice in the management of narcolepsy (2). The pattern of diurnal variation per se did not differ significantly from the control group, and it is suggested that the variations in serum serotonin value and the therapeutic response may be related to pharmacologic actions of ergotamine. Serotonin metabolism in the brain has an important role in the hypothesis of arousal-sleep mechanisms (3), and the facts of lowered serum serotonin concentration and alleviation in manifestations of narcoleptic paroxysms do not seem to be in conflict with this hypothesis.

Although ergotamine has generally been believed to be in all likelihood devoid of significant effects on the CNS (except its activity of stimulating the vomiting center), it might be conceivable that ergotamine or its metabolite interferes with serotonin metabolism in the brain of narcoleptics, given its noticeable structural similarity to its competitive analogue, LSD. Studies designed to explore this possibility are in progress.

Proper Knowledge of Psychotropic Medications

SIR: In their article "The Physician's Knowledge of Psychotropic Drugs: Preliminary Results" (January 1978 issue), Richard M. Gottlieb, M.D., and associates did well to show that psychiatrists and psychiatric residents had very low levels of knowledge about the physiology, pharmacology, and side effects of the most commonly prescribed drug in America, diazepam (1). However, this should in no way lead one to believe that psychiatrists are not interested in learning about proper psychotropic prescribing.

Recently, at Brotman Memorial Hospital, a survey designed by the pharmacy department to measure psychiatrists' journal preferences was sent to 160 psychiatrists on our staff. Of the respondents, 89.7% of the psychiatrists submitted that they would appreciate a "hospital" newsletter containing abstracts of important psychopharmacological issues and latest developments. The pharmacy department subsequently developed a monthly two-page newsletter to meet this request. All of the major medical journals as well as 24 psychiatric journals are reviewed for psychotropic-related articles which are then summarized and incorporated into the newsletter.

We feel, as Dr. Gottlieb and associates concluded, that the challenge of teaching proper use of psychotropic medications "may not be met in medical education today and that training programs be upgraded to meet this need." It must be remembered, moreover, that learning is an ongoing process which must be continually updated. With such a voluminous amount of psychiatric literature to read and a great number of patients to see, one can easily understand how a psychiatrist may lag behind in updating his knowledge of psychotropic drug usage. Thus, a brief hospital newsletter reviewing the current literature is one way to meet the continuing education needs of psychiatrists by helping them to keep abreast of important psychopharmacological issues.

Culver City, Calif.

Cinchonism in a Patient for Whom Lithium Was Prescribed

SIR: A 40-year-old banker was begun on lithium carbonate for hypomania. He was maintained on two 300-mg tablets t.i.d. A serum lithium level obtained on Monday morning was 1.0 mEq/liter. Monday evening, the patient opened a new bottle of the medication he had just obtained from the pharmacy. Tuesday afternoon, the patient thought that some fellow employees were laughing at him. Wednesday morning at 5:00 a.m. the patient awoke and began to believe that he was about to lose his job, his house, and his family because of his illness. At work, he continued to be anxious, fearful, and depressed. To his supervisor, the patient's appearance was similar to that observed 5 weeks previously, when the patient had first been hospitalized. The patient called his psychiatrist, who advised him to try to stick it out another 24 hours until his next scheduled appointment but to come in if the problem became more intense.

The mystery was solved a few minutes later when the pharmacist discovered that he had accidentally substituted 200-mg quinidine tablets for the lithium. The pharmacist reported that the quinidine bottle and tablets were similar in appearance to the lithium bottle and tablets and that the two bottles were side by side on the stock shelf. On subsequent questioning, the patient admitted to severe tinnitus.

The patient was advised to discontinue the quinidine and to see his family physician. He recovered within 24 hours and has since been asymptomatic on 1800 mg/day of lithium carbonate.

Cumberland, Wis.

Differentiating Grief, Mourning, and Bereavement

SIR: "The Grieving Spouse" (January 1978 issue) by Milton Greenblatt, M.D., is a useful compilation of several well-known statistical and clinical studies of grief and mourning.

One of the difficulties I encountered in reading his article, however, was the almost interchangeable use of the terms "grief," "mourning," and "bereavement." One heading in the article suggests that there might be a distinction between these terms: "Grief as a Process and the Phases of Mourning," but unfortunately this distinction is never clearly spelled out.

In my own clinical practice I have found it helpful to distinguish between grief and mourning as follows: Grief is the sequence of affective, cognitive, and physiological states that follows directly after an irretrievable loss; mourning, on the other hand, is a complex and lengthy process that begins with denial of the loss and, in its optimum course, proceeds toward the acceptance of both the external loss and the integration of multiple intrapsychic shifts (1).

The clinical distinction between grief and mourning was anticipated by Freud (2) in an addendum to his paper on anxiety in which he characterized grief as a "longingful cathexis" toward the lost object. Bowlby (3), whose work on childhood separation experiences is often quoted and summarized, also studied the literature on loss reactions in animals and noted that a substantial portion of behavior in primates who had lost siblings and parents related to seeking and retaining nurturing support from their immediate environment. Such behavior appeared to be defensive and protective and might be phylogenetically related to the heightened sympathetic response observed by Parkes (4). If the clinical distinction between grief and mourning is valid, then the process of grief would appear to serve the function of protecting the organism and preparing it for the longer process of mourning. In humans, grief might well hold the same relationship to mourning as anxiety does to the mobilization of defense mechanisms, namely, a necessary preparation.

The usefulness of such a distinction becomes apparent when applied to three conditions that Dr. Greenblatt mentioned in his article: delayed, suppressed, and pathological grief; and a fourth one described by Helene Deutsch (5), absent grief. These conditions should be understood not as isolated pathological phenomena but as abnormal or maladaptive defensive maneuvers that occur in individ[illegible] backgrounds, psychodynamics, and persona[illegible] Thus a schizophrenic might experience an ab[illegible] predominantly somatized grief reaction and [illegible] longer process of mourning, the reason being [illegible] never attained the developmental milestone [illegible] constancy. By contrast, an obsessive neuro[illegible] pass through normal grief but founder in the [illegible] ess because of excessive ambivalence tow[illegible] spouse. The main point of these examples is t[illegible] logical" nature of the process would depe[illegible] more on the preloss state of functioning than [illegible] timing, level of affective expression, verbal [illegible] gruence with social expectations observed in [illegible]

BOOK REVIEWS

Psychotherapy Versus Iatrogeny: A Confrontation for Physicians, *by Nikola Schipkowensky. Detroit, Mich., Wayne State University Press, 1977, 494 pp., $30.00.*

Although this book is expensive, it is well worth the investment. It is a most interesting book divided into eight sections discussing different aspects of iatrogeny. The first section is an excellent historical review, including references to Hippocrates and Plato and emphasizing that Hippocrates recommended wise restraint in speaking about the dangers of health and life in the presence of the patient to avoid "iatropsychogeny." Schipkowensky then discusses iatrogeny in German, French, Anglo-American, and Slavic psychiatry, pointing out that there is relatively little emphasis on the pathology caused by physicians' attitudes.

He discusses hypnotism as an example of the danger of new psychotherapeutic methods and refers to a number of theories put forward by those using "magnetism." Leibault and Bernheim reported cures of 95% of their patients, while Janet had a complete recovery in relatively few (7%) of his hypnotically treated patients. (It was my good fortune in 1936 to spend some time talking with Janet about hypnotism. Perhaps part of his lack of success was his questioning attitude about hypnosis.)

In a fascinating chapter titled "The Physician and Belles Lettres" Schipkowensky describes Montaigne as "the founder of theoretical antimedicine." He then describes in considerable detail many other authors who rejected medicine in principle. He points out that "a genuine doctor is not afraid of the mirrors in which many authors want to show him his image; however, he has the right to demand a realistic reflection, both of his science and of his activity. . . . A true mirror keeps the doctor from iatrogenic and iatropathic mistakes." In referring to various literary criticisms of physicians, the author points out that all physicians are threatened by this potential and that, as a result, all physicians should be extraordinarily careful not to take advantage of their patients in any way.

The chapter on the ideology of iatrogeny provides a somewhat philosophical point of view, with particular reference to magic and its power to produce disease and even death. Schipkowensky also discusses religious iatrogeny, focusing on religious cures as well as on the development of disease through guilt concerning sins. He provides a long discussion of Freudian psychoanalysis as a "model of psychotherapeutic iatrogeny." He gives Freud credit for a brilliant mind and "cleverness in neutralizing his critics as one who functions best in adversity." He is particularly critical of the transference theory: "To interpret all interpersonal relations as transference phenomena is one of many assertions Freud made without any foundation" (p. 143).

In his section on organolocalistic (mechanistic) iatrogeny the author reviews the literature from ancient times to the mid-twentieth century in a very interesting way, giving several examples of the way in which physicians can cause anxiety symptoms by resorting primarily to apparent physical findings. In the section on character and iatrogeny he discusses personality as material (somatic) in content, ideal (psyche) in its form, biological in its origin, and social in its development. When physicians criticize each other in the patient's presence concerning diagnosis, treatment, and prognosis, they do great harm to the patient. With this we could certainly all agree.

As a logical succession to ideology, the author's next chapter deals with methods of communicating medical topics that may do more harm than good. He points out that medical students often develop symptoms discussed in lectures or at the bedside. By the same token the physician's attitude or a careless word may plant the seeds of a serious anxiety or a phobic attack. He presents many case histories demonstrating how physicians, by inadvertent comment or by presumptive diagnosis, may cause a patient to believe that there is a serious condition present. On the other hand, the author points out that some patients cannot be told the true nature of an incurable condition.

In the chapter on clinical iatrogeny the author states that anxiety neurosis "evolves" in three clinical forms: phobia, hypochondriasis, and apprehension of harm to the individual's social values. He includes neurasthenia as a pathological reaction of personality, as well as hysteria, which he describes as psychotic in pattern when its existence is questioned. He describes cases in which symptoms of these conditions resulted from an inappropriate treatment procedure carried out by physicians. Patients with psychosomatic and physical diseases who hear inappropriate comments by a physician may also develop iatrogenic reactions that cause their symptoms to be more severe. He believes that "psychogenous death" occurs more frequently than is usually believed, especially when the patient feels he or she is in a hopeless situation.

Under the heading "Anti-Psychiatry" Schipkowensky describes in detail Rosenhan's article "On Being Sane in Insane Places" (1). If Schipkowensky were alive today I am sure he would have included the ABC television program "Madness and Medicine" as an unfortunate production with a substantial antipsychiatry bias. In such instances there is just enough substance for the psychiatrist to be aware of some important facts, as he or she would from Rosenhan's article, yet enough misinformation that it could result in serious harm. This section of the book is of particular interest, especially the author's comments about Szasz and his writings.

In the section on the occurrence of iatrogeny in psychotherapy the author devotes a great deal of space to both direct and indirect criticism of psychoanalysis, especially Freudian psychoanalysis. He presents a long and interesting discussion of "psychogeny" in the home and school under the heading of "didascalogeny and mathetogeny." He emphasizes the selection of good teachers because, with parents, the teacher represents the greatest influence on a child at a time when his or her personality is most easily molded. Schipkowensky describes cases in which teachers have exercised a serious negative influence, resulting in psychiatric symptoms. He discusses parental influences under the head-

ing of "Oppressive and Excessive Didascalogeny" and gives many examples of this type.

In the chapter on liberating psychotherapy the author summarizes the aims of psychotherapy as follows: 1) healing of pathological reactions of the patient's personality, 2) stimulation and the making of a harmonious personality in pathological developments, 3) rehabilitation after changes of character and/or disability in process psychoses and in somatic disease, 4) readaptation of antisocial and asocial individuals to the community of life, 5) rehabilitation of all mental patients, aiming at complete maturing of their personalities by widening their spiritual horizon, 6) alleviation of the condition of incurable patients and spiritual assistance to those doomed to long agony. This is a very interesting chapter and well worth reading.

In Schipkowensky's very short chapter "Conclusion" he makes a particularly important point: "Whatever the kind of treatment the psychic influence of the physician on healthy individuals as well as sick ones cannot be ignored" (p. 476). This influence, of course, can be either positive or negative. He points out that iatrogeny is sometimes embedded in a healer's personality; therefore, physicians should always have as much self-knowledge as possible and should judge the patient's personality so that they can treat the patient in accordance with his or her personality peculiarities.

This book is a very important contribution and should be available to every physician as well as to others who do psychotherapy. I would express one serious criticism of the book—Schipkowensky's bias against psychoanalysis. This book would be valuable even if used only for reference to the very extensive bibliography Schipkowensky provides. Although written in a very readable way, the book is so extensive that it should be used as a reference work.

RAYMOND W. WAGGONER, M.D., SC.D.
Ann Arbor, Mich.

Female Psychology: Contemporary Psychoanalytic Views, *edited by Harold P. Blum, M.D. New York, N.Y., International Universities Press, 1977, 438 pp., $22.50.*

Freud (1) concluded his lecture on femininity with the statement that his knowledge of the subject was incomplete. He advised those who wished to know more about it to wait until science could offer deeper and more coherent information. On the basis of new information, the contributors to this volume have evaluated and revised Freud's theories and offer perspectives of their own.

Several of the authors in this book disagree with Freud's assumptions that female identity is not established until the child has passed through the phallic phase and that her entrance into the oedipal phase at about age three is based on her discovery that she has no penis. They cite evidence that feminine gender identity is established early in life and is determined by the interaction of anatomy, biology, parental attitudes, and the child's capacity to organize internal and external experiences. There is some disagreement as to the relative importance of these factors, especially the impact of the absence of the penis, although all agree that it is a significant factor in the resolution of the young girl's [illegible] plex.

Galenson and Roiphe differ with Freud [illegible] which a girl becomes aware of genital differ[illegible] lieve this occurs during the pre-oedipal st[illegible] and 18 months), but they agree with him that [illegible] castration anxiety are major organizers of t[illegible] women. To Kleeman, parental attitudes and [illegible] nitive development are most important. Sto[illegible] importance of parental sex assignment and o[illegible] titudes, and he also notes the impact of a b[illegible] in the establishment of femininity. From [illegible] tions of three little girls, Parens and associa[illegible] the girl's oedipal phase is not initiated by c[illegible] but is associated with gender-related chan[illegible] with the nature of her object relations, and [illegible] dispositions. The wish to have a baby, the [illegible] pendent on the wish for a penis.

Clower's observations about pleasurable [illegible] girls during latency challenges Freud's ass[illegible] relinquishment of pleasure in her body is a [illegible] the establishment of femininity. According [illegible] transition from adolescence to womanhood [illegible] resolve her ambivalent ties to her parents i[illegible] her wish to be a mother. The tendency to c[illegible] hood in contemporary society is a reality fac[illegible] es the difficulty in establishing a feminine [illegible] berg presents suggestive evidence that duri[illegible] ner genital sensations, which in early life ha[illegible] a sense of femininity, are reintegrated inte[illegible] femininity.

Societal attitudes toward women are com[illegible] to understand. Lerner suggests that the adul[illegible] the child of the female genitalia is evidence [illegible] discomfort associated with female sexuality [illegible] women, especially of their procreative cap[illegible] ject of a paper by Jaffe. Although society's [illegible] women is clearly ambivalent, the tendency [illegible] has gained support from Freud's characteri[illegible] as inferior, narcissistic, and masochistic. S[illegible] ception to this view, demonstrating its origi[illegible] oretical and social biases. Blum examines [illegible] female masochism and moral inferiority ar[illegible] they are derived from unwarranted notio[illegible] sexuality. For Grossman and Stewart, penis [illegible] phor that can reflect disappointment and ra[illegible] at various levels of psychosexual developm[illegible] as a symptom to be analyzed and not a m[illegible] ultimate conflict. The interaction between [illegible] and other determinants of femininity is [illegible] Ticho's paper on autonomy and Applegarth[illegible] bition.

In his discussion of female orgasm, Moor[illegible] ing point that conclusions about the nature [illegible] ences based only on direct observations are [illegible] It is necessary to know the psychic repres[illegible] ated with the orgasm in order to understand [illegible] servations about sleep orgasms support the [illegible] may have varied meanings. Barglow and Sc[illegible] cal of the literature on women that relies too [illegible] ological data and does not consider intrapsyc[illegible] explain the conditions of women.

The comprehensive view of the multiple [illegible] female psychology presented in this book [illegible] definitive statement about what female ps[illegible] should be is not possible. The many facto[illegible]

femininity can be integrated into varied patterns. This perspective can facilitate the efforts of the therapist to assist the female patient in resolving her conflicts and establishing an identity that suits her. Although this book offers many valuable insights, the tentative nature of some of the reported findings suggests that there are areas for future investigation.

Marihuana Research Findings: 1976. NIDA Research Monograph 14, *edited by Robert C. Petersen, Ph.D. Rockville, Md., National Institute on Drug Abuse, 1977, 225 pp., no price listed.*

Physicians, particularly psychiatrists, are often asked for expert opinions on matters with social and political consequences. If the issue is outside our expertise, we should say so; if we are merely ignorant, we should either discover the known or investigate the unknown. When we speak, we should be careful to distinguish our expert opinions from our voices as independent citizens.

One area in which psychiatrists profess expertise is the impact of drug use on physical and psychological health. Because of the strong and emotionally held opinions in this area and its importance in many lives, a broad and secure data base is essential, particularly with regard to the so-called recreational drugs. Until recently, the public debates about decriminalization of marijuana were lacking in information. However, as *Marihuana Research Findings: 1976* evidences, the debate has spawned numerous projects (many supported by the National Institute on Drug Abuse) and, at last, some hints of useful information.

Following an introductory and summarizing chapter by the editor, this volume contains detailed reviews of the epidemiology of marijuana use; its chemistry, metabolism, toxicology, pharmacology, and acute and chronic effects on unlearned and learned animal behavior; and its effect on humans, with special attention given to the genetic and immune systems as well as to therapeutic potential. These are written in clear, simple English by active, expert researchers. Even the descriptions of metabolism and toxicology were clear to me.

The use of marijuana has markedly increased since the late 1960s, spreading from the counter culture to a broad cross-section of youth—a majority of those 18 to 25 years old have used the drug. It appears to have moved from fad to cultural pattern. If the user avoids such tasks as driving while intoxicated, occasional or minimal regular use of marijuana as a social euphoriant has not been shown to have lasting deleterious effects. Nor does marijuana use inevitably lead to use of other, more dangerous illicit drugs or to violent or criminal behavior. As with the use of alcohol and tobacco, frequent use of high potency compounds may be associated with deleterious effects that have not yet been demonstrated. In addition, idiosyncratic physiological and psychological responses may occur.

This brief summary does not do justice to the rich content of this slim, readable book. It is an important volume for all of us in our roles as experts and citizens. I eagerly await the next annual report.

WILLIAM A. FROSCH, M.D.
New York, N.Y.

Cognitive-Behavior Modification: An Integrative Approach, *by Donald Meichenbaum. New York, N.Y., Plenum Press, 1977, 293 pp., $14.95.*

Cognitive behavior modification deals with the intrapsychic or cognitive aspects of behavior therapy and is a recent, important thrust within the field (1–4). This area of behavior therapy is so new that it has not been included in two recent comprehensive reviews of psychiatry (5, 6).

The book is a theoretical study heavily dependent on Meichenbaum's own research. The first three chapters concern the technique of self-instructional training. This technique has been successfully applied in the treatment of hyperactive, impulsive children, socially isolated children, and adult schizophrenic patients. In the fourth chapter Dr. Meichenbaum stresses the importance of cognitive factors in systematic desensitization, modeling, assertive training, and aversive conditioning. He presents evidence suggesting that the traditional behavior therapy techniques would have their clinical effectiveness improved if cognitive techniques were integrated into the treatment plan.

The technique of stress inoculation training (a method used to enable patients to better deal with stress), which has been successfully applied to phobics, alcoholics, and socially withdrawn children, is discussed in chapter five. In chapter six, Dr. Meichenbaum compares his cognitive restructuring techniques with those of Aaron Beck, Albert Ellis, Thomas D'Zurilla, and Marvin Goldfried. In chapter seven there is a discussion of internal dialogue (what the patient says to himself or herself) and its importance in both behavior change and the human body's physiological response to stress. Dr. Meichenbaum presents his cognitive theory of behavior change in chapter eight, and in the last chapter he provides a method of assessing patients that uses internal dialogue and images (fantasies) as the primary data.

Dr. Meichenbaum sets forth not only firm experimental support for his techniques but also a practical guide as to how to assess and treat patients within the framework of cognitive behavior modification. He offers convincing evidence for adding cognitive behavior modification skills to our present regimen.

This book is not a comprehensive review of the literature, and little time is spent on thought stopping, covert sensitization, covert reinforcement, covert extinction, and attribution theory. Despite these omissions, the book is well written and offers additional clinical strategies that all psychiatrists could use.

Essays in Neurochemistry and Neuropharmacology, Vol. 1, *edited by M.B.H. Youdim, D.F. Sharman, W. Lovenberg, and J.R. Lagnado. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1977, 195 pp., $21.50.*

The explosion of research and knowledge in the neurosciences has been paralleled by an abundance of new books and journals to record recent successes and provide portents of the future. It is no longer uncommon to convene international conferences for the major purpose of producing one or more volumes, to be rapidly published by photo-offset, lest the information contained be obsolete before it reaches its audience. It is in this context that *Essays in Neurochemistry and Neuropharmacology* must be considered, especially since it is the first of what will be a very large series indeed, judging from the articles planned for future volumes.

The projected series is aimed at researchers and graduate students "who wish to familiarize themselves with current specific problems in neurochemistry and neuropharmacology." The aim is for each article to represent a more personalized statement by the author(s), including the author's own views on trends for future research.

This first volume consists of six articles. J.M. Saavedra discusses the role of methylating enzymes in the synthesis and catabolism of compounds relevant to the nervous system. G.G.S. Collin deals with the role of the sulfated amino acid taurine in the mammalian CNS. H. Thoenen and A. Otten write on the molecular basis of transsynaptic regulation of the synthesis of macromolecules. K.F. Tipton and associates describe the role of aldehyde metabolites of biogenic amines in the brain. A.J. Kastin and associates discuss CNS and pituitary effects of hypothalamic peptides and melanocytes-stimulating hormone. Finally, E.D. Bird and L.L. Iversen review neurochemical research in Huntington's chorea.

Judging from these six articles, the editors were only partially successful in achieving their aims. The depth of scholarship is by and large appropriate for an introduction to new areas for advanced students or researchers. References are limited in most articles, but they are still abundant enough to enable an interested reader to get a good start on the primary literature. (Examination of the references, however, reveals that most of the articles were probably completed in early 1976—two years ago. A publication lag of this magnitude hampers but does not eliminate the worth of this type of volume, which is aimed at giving readers a good start in a field.) The articles contain elements of the kind of essay the editors hoped for, but they are usually only appendages to the main business of reviewing the literature. However, some of the more personal remarks are of a high order, especially Thoenen and Otten's discussion of the role of transsynaptic regulation in the adaptation and plasticity of the nervous system.

All of the reviews are well written, and it is probable that the book would be useful to readers interested in this field. The authors and editors have been highly successful in producing readable, clear, concise statements [illegible] without getting lost in minutiae. They also [illegible] uncertainty.

Future volumes in the series will include [illegible] on the biochemistry of mental illness, [illegible] chemistry, and mode of action of indoles [illegible] cinogens. These might be of greater inter[illegible] psychiatrist who would like an introduction [illegible] search in the neurosciences.

HERBERT Y. M[illegible]

Family Constellation: Its Effects on Personality and Behavior, 3rd ed., *by Walter Toman, Ph.D. New York, Springer Publishing Co., 1976, 325 pp., $[illegible] paper).*

Dr. Toman outlines the natural environment in which brothers and sisters influence each other's personality development, describes basic trait clusters for ten sibship positions, gives guidelines for generating additional categories, and expounds a fascinating and heuristic theory of complementarity (attraction of unlikes) of sibships in relation to marriage, parent-child interactions, and [illegible] achieves quantification of the measures of sibship [illegible] conflict and of the effect of loss of a family member, expressing, in algebraic terms, the degree of [illegible] flict and the disorganization of constellations, [illegible] so provides a complete and valuable interview guide for securing sibship constellation data. Three case histories illustrate how the personality trait clusters obtained by retrospective sibship constellation and related data (e.g., change of family, change of residence, illnesses, secession, religion) can be used in consultation regarding [illegible] vocational goals, and general effectiveness [illegible]

Because of weaknesses in the research design and statistical analyses of the experimental data [illegible] ing the theory of attraction of complements [illegible] gories and because of the diametrically opposite [illegible] experiments by other researchers, the most [illegible] sumption one can make from this book is [illegible] and direction of the influence of complementary [illegible] constellations on the compatibility of marriage [illegible] ships have not been firmly established. Descriptions of personality trait clusters demand the use of unambiguous, precise, culturally unbiased adjectives, a difficult task. Toman's colloquial style often fails to meet [illegible] determined, he has derived the trait clusters [illegible] ing clinical observations rather than experimental [illegible] to support his statements. The procedure of [illegible] ality traits of sibship categories in sibships [illegible] from combinations of constellations of sibships [illegible] warranted. The discussion of the effect of [illegible] spacing between siblings is in each case inadequate.

Toman's treatise on family constellation would have been improved considerably had he included descriptions of child-rearing practices by which, for example, the youngest child could be given some of the leadership qualities of the eldest and the eldest some of the "freedom" of the youngest. Educators would appreciated specific discussion of preventive methods, and psychotherapists would have welcomed discussion of differential treatment approaches [illegible] ship constellation effects.

From the studies and experiences of a lifetime, Toman has produced a volume full of sagacious insights, suggestive material for the psychotherapist and educator, and heuristic hypotheses for the behavioral science researcher.

HERMAN J.P. SCHUBERT, M.E., PH.D.
Buffalo, N.Y.

Current Developments in Psychopharmacology, Vol. 4, *edited by Walter B. Essman and L. Valzelli. New York, N.Y., SP Books (Spectrum Publications), 1977, 264 pp., $25.00.*

This volume is one of a series of annual publications consisting of invited contributions from distinguished scientists and clinicians actively working in different areas of psychopharmacology. Volume four has nine chapters; four deal with basic or preclinical issues and five deal with clinical problems.

One of the most informative chapters of the book is that of Simon on the distribution and properties of opiate receptors in the CNS and the identification and characterization of endogenous ligands, endorphin peptides, for opiate receptors. On the basis of these new findings, systematic studies have been directed to provide evidence for a qualitative or quantitative change in opiate receptors during chronic treatment of animals with opiates, but the question of how opiate receptors in the brain are affected by the development of tolerance and physical dependence has remained open. In the meantime, as discussed by Blasig and Herz, precipitated opiate withdrawal in rats seems to offer a suitable alternative approach for studying problems concerning physical dependence. Since the problem of precipitated withdrawal depends in part on the kind of antagonist applied, the precipitated withdrawal method may become a useful link between molecular and behavioral approaches to the study of opiate dependence.

The possible role of catecholamines in the regulation of various central nervous functions and behavior has been reviewed with emphasis on information important for the mode of action of some psychotropic drugs. Although further support to the view that schizophrenic symptoms may be mediated via dopamine-carrying neurons is given, Engel and Carlsson, on the basis of some new experimental data, put forward the hypothesis that there is a common neurochemical basis, involving the catecholamines, for the primary reinforcing properties of dependency-producing drugs. Considering that the catecholamine neurons form a great number of neuronal pathways in the brain, the majority of which originate in the lower brain stem projecting to widespread areas of the brain and the spinal cord, it is not inconceivable that catecholamines are involved in the regulation of various behavioral and physiological responses and conditions, such as drug dependence and schizophrenia.

Identification of an enzyme capable of using cofactor 5-methyltetrahydrofolate in producing tetrahydro-β-carbolines from tryptamine analogs resulted in a new interest in the biological effects of naturally occurring (e.g., harmine, harmol, harmaline, harmolol, yohimbine) and synthetic (e.g., 2,9-dimethyl-β-carbolinium iodide, usually referred to as DMCI) β-carboline substances that in the past had been studied only because of their hallucinogenic, tremor-inducing, and monoamine-oxidase-inhibiting effects. Although the enzymatic formation of tetrahydro-β-carbolines remains to be demonstrated in vivo, Ho believes that the new findings reopened the possibility that a psychotic state may result from a shunt of the metabolic pathway of serotonin and the consequent formation and accumulation of a psychotomimetic compound.

There is a short and concise chapter on recent advances in genetics with psychopharmacological significance. Of particular clinical relevance are findings related to genetic factors that seem to influence the response to alcohol and the therapeutic responsiveness to lithium salts, monoamine oxidase inhibitors, and tricyclic antidepressants. On the basis of the steadily accumulating data, Mendlewicz asserts that "a knowledge of the contributions of genetic and environmental influences in drug metabolism and drug response is an essential research area that will hopefully lead to the discovery of predicting factors in the determination of success or failure of treatment."

This volume also contains a comprehensive review of the toxicology of tricyclic antidepressants by Fiori, a critical review of long-term treatment with neuroleptics by Shepherd and Watt, a long-overdue review of the pharmacological management of hyperkinesis by Silbergeld, and a review of current trends in the psychopharmacology of aging by Sathananthan, Ferris, and Gershon. According to Silbergeld, "hyperkinesis" denotes a diverse group of behavior disorders in which some order can probably be imposed by separating hyperkinetic children according to their pharmacological response. Amphetamine- and methylphenidate-responsive hyperkinesis is one of the most systematically studied subtypes, and extrapolation from the experimental pharmacology of these drugs has led to the original hypothesis that decreased monoaminergic function is the underlying defect at least in certain hyperkinetic states. The fundamental problem with this hypothesis is that the mechanisms of experimental hypermotility and the reversal of amphetamine's behavioral stimulation are not compatible. The conjunction of altered response to amphetamine and hypermotility has not been experimentally produced except in one case of chronic exposure to inorganic lead, which is associated with reduced acetylcholine release and increased catecholamine functions. Whether this new model of hyperkinesis offers any advantages over the existing ones remains to be seen.

In summary, this convenient volume gives a good selection of articles on current developments in psychopharmacology. Although written primarily for the teacher and research worker rather than for the student, some of the chapters contain material that could help the practicing psychiatrist in his or her everyday work.

THOMAS A. BAN, M.D.
Nashville, Tenn.

Primer of Lithium Therapy, *by James W. Jefferson, M.D., and John H. Greist, M.D. Baltimore, Md., Williams & Wilkins Co., 1977, 206 pp., $10.50 (paper).*

Although not quite ready to say, "If you know lithium, you know psychiatry," one is impressed by the number of areas of psychiatry involved in the study of this simple element. Not only is there an abundant literature detailing its physiology and pharmacology, lithium research and clinical use have also stimulated investigation in such apparently diverse areas as genetics and forensic psychiatry. Its clinical use is prompting a thoughtful reassessment of time-honored assumptions about diagnostic groupings as well as of the relationship between diagnosis and etiology.

This clearly written book, packed with carefully evaluated

summaries, is a noteworthy addition to the exponentially increasing lithium literature. Drs. Jefferson and Greist have done the clinician a singular kindness by providing well-organized information from their Lithium Consultation Computer Program. The summaries of relevant articles are valuable in their own right, but the authors' analysis is invaluable.

Among the many positive aspects of this book is the thorough discussion of differential diagnosis and its importance in terms of predicting both therapeutic response and lithium toxicity. The authors update the recommendations concerning the physical and laboratory evaluation of the patient for whom lithium is considered. They go beyond the usual warnings about drug interactions and offer pragmatic suggestions about the management of patients with complex pharmacological needs. The section on the treatment of lithium intoxication is up-to-date, discarding approaches that, although theoretically sound, have proven of little practical value. The authors' suggested guidelines are particularly welcome because few of us have obtained first-hand experience in the treatment of a large number of patients with severe lithium intoxication.

In a book such as this there have to be a few things that one would like included or developed more extensively. The authors indicate that lithium may be an effective antidepressant in certain instances, but they do not comment on the studies comparing lithium with tricyclic antidepressants. The chapter on the general pharmacology of lithium is not of the same quality as the other sections, in part due to its brevity. However, several good references on this subject are given.

I have one, perhaps gratuitous warning: in our search for certainty in an uncertain world, we long for *the* definitive text. This one is excellent, but it will soon be dated as additional information becomes available about the long-term benefits and hazards of this important pharmacological agent.

CHARLES W. BOREN, M.D.
Hartford, Conn.

Psychiatric Medicine, *edited by Gene Usdin, M.D. New York, N.Y., Brunner/Mazel, 1977, 486 pp., $20.00.*

This book is a consolidation of papers presented at the annual scientific meeting of the American College of Psychiatrists in February 1977. To some browsers the title would suggest a general textbook of psychiatry. In this instance, however, "psychiatric medicine" encompasses the topics of psychosomatic or psychophysiological psychiatry, with special attention to the field of consultation and liaison psychiatry.

The book is divided loosely into sections such as Psychobiology and Liaison Psychiatry, but it is basically a series of papers on special topics. This gives an initial impression of fragmentation. It is only after concluding the book that one is aware that, taken as a whole, it is a good overview of historical trends and special topics of current interest. Portions of the book would appeal only to special interests, but the reader who completes the whole volume has a working knowledge of the field and is equipped to explore in depth a number of significant areas. As Martin states in his epilogue, "This meeting of the College reported no one great discovery, but maturely presented concepts of illness and health based on sound data."

Behavior Therapy in Clinical Practice: Deci... cedure and Outcome, *by Ernest G. Poser P... Ill., Charles C Thomas, 1977, 164 pp., $13...*

Over the last decade more than a dozen ... been published on the theory and practice o... py. Some of these stress basic principles ... others stress specific behavior therapy pro... grams as they apply to psychiatric disorders ... able volume has a different focus and organ... describes eight specific inpatients who we... behavioral unit he directed at the Douglas H... Montreal, Que., Canada.

Each case is described in some detail, ... tient's family background, personal history, ... the problem dealt with. Dr. Poser then prov...

analysis of the patient's difficulty, which may include behaviorally oriented tests, a delineation of the treatment goals, and a description of the various treatment methods employed. An important aspect of these case reports is an evaluation of the effectiveness of each treatment component along with a follow-up evaluation, which in most cases extends from 5 to 10 years. The latter is unusual in case reports and of great value, even though these are selected cases.

This book gives the reader a perspective on the outcome of behavior therapy with patients sufficiently impaired to require hospitalization and also provides information on possible cycles in the patient's maladaptive behavior and the need for early intervention should relapse occur. The eight cases provide the author an opportunity to describe the application of 15 different behavioral procedures, since some patients required more than one approach. These range from relaxation methods and modified systematic desensitization for the treatment of phobic states to aversive conditioning and differential social reinforcement for the amelioration of such socially disapproved behaviors as sexual exhibitionism.

This volume is not a substitute for a text that develops in a systematic and comprehensive way the basic principles of learning and social conditioning. Nor does it take the place of a text that describes the chief behavior therapy procedures for the treatment of various disorders. Rather, it complements such texts by providing in greater detail than one usually finds a description, behavioral assessment, plan of treatment, and follow-up of a number of patients. This conveys vividly to the reader the essence of a behavioral approach to specific problems impeding the restoration of functioning in hospitalized psychiatric patients.

JOHN PAUL BRADY, M.D.
Philadelphia, Pa.

Clinical Biofeedback: A Procedural Manual, *by Kenneth R. Gaarder, M.D., and Penelope S. Montgomery, M.S. Baltimore, Md., Williams & Wilkins Co., 1977, 222 pp., $12.95 (paper).*

This is one of the first books about the practical aspects of clinical biofeedback training. Gaarder and Montgomery have had an active clinical biofeedback practice at the University of Texas at San Antonio. In this book they draw on their extensive clinical experience to give us a working account of the biofeedback training process.

This book aims to provide enough information on biofeedback training to enable practitioners to incorporate biofeedback techniques into their clinical work. The book begins with a consideration of the scientific foundations of biofeedback in experimental laboratory studies. It then moves on to practical considerations, including choice of patients for biofeedback training, structuring a treatment program, assessment of ongoing therapy, and treatment strategies. Two final chapters are of particular interest to readers with relatively little background in electronics. One deals with instrumentation techniques and the other with the function, safety, and specifications of various types of biofeedback equipment. Three useful appendices are included: a list of professional resources in the biofeedback area, questionnaires routinely used in training, and a script for relaxation training.

Gaarder and Montgomery's major theme is that successful biofeedback treatment depends on many factors common to other therapy approaches. Biofeedback is not presented as some form of fancy electronic panacea. Rather, it is discussed as a method of behavioral intervention that needs to be placed in the context of psychotherapy. For example, the need to develop a therapeutic relationship with the patient is strongly emphasized. In addition, practitioners are encouraged to take into account the patient's environment and such related factors as secondary gain, competing behaviors, and the role of significant others. The stress placed on the complexity of clinical biofeedback training is refreshing. Most practicing biofeedback clinicians realize that, as Gaarder and Montgomery point out, the simplicity of such training is more illusory than real.

A second theme receiving a great deal of attention in this book is the need to use biofeedback in combination with other procedures, such as relaxation or autogenic training. The authors note that a combination of procedures often facilitates transfer of skills learned in the laboratory to the patient's natural environment.

One question about the entire clinical biofeedback area that applies equally to this book is, Can the physiological changes achieved through biofeedback training be attributed to feedback itself? When a broad comprehensive approach to patient care such as the one outlined in this book is employed, it is difficult, if not impossible, to determine which elements of the treatment package are responsible for behavior change.

The major weaknesses of this book stem primarily from the fact that biofeedback is a relatively recent area of research and practice. Data on many of the problems discussed in this book (e.g., selection of patients) are only now becoming available.

Many clinicians will find this book helpful as a practical handbook. In and of itself, the book does not provide the detailed coverage of the biofeedback area needed by someone seriously interested in applied clinical research. The book is clearly and concisely written and could be used as a training manual for technicians or research assistants. It meets the pressing need for making practical information on biofeedback training readily available to the medical community.

The promise of biofeedback is that it may provide a mechanism for the behavioral treatment of medical disorders. It is clear that the practical problems delineated by Gaarder and Montgomery need to be systematically addressed before this promise is fulfilled.

FRANCIS J. KEEFE, PH.D.
Boston, Mass.

Ethical Issues in Sex Therapy and Research, *edited by William H. Masters, M.D., Virginia E. Johnson, and Robert C. Kolodny, M.D. Boston, Mass., Little, Brown and Co., 1977, 219 pp., $12.50.*

This book is the report of a conference sponsored by the Reproductive Biology Research Foundation held in January 1976. The participants were all distinguished scientists, moralists, and mental health professionals. The topics were wide-ranging but largely focused on the concerns involved in research on sexual matters as well as the moral and ethical problems in sex therapy. It is a significant contribution to our understanding of the burgeoning issues that have emanated from the epochal contributions of the sex researchers, from Freud to Masters and Johnson, that have revolutionized the attitudes of the practitioner as well as the public with regard to sex behavior. The widespread use of the techniques of sex

therapy that have grown out of these developments raises a number of moral and ethical issues in the practice and training of sex therapists. Who should be a sex therapist and how should he or she be trained? What are the problems of anonymity, confidentiality, informed consent, and insurance coverage? Many far-reaching consequences have grown out of advances in dealing with sexual dysfunctioning. This volume touches on all of these matters and deals with them intelligently and cogently.

It was generally agreed at the conference that research in sex behavior does not differ in any real sense from research or experimentation in other biochemical or behavioral contexts. It requires the full understanding of the issue of informed consent and the other safeguards of responsible investigation. This means a valid research design that is aware of the prevailing cultural attitudes toward sex behavior. There was a range of viewpoints expressed by the participants on all of these questions.

There was also agreement on the unique situation in sex therapy for the possibility of patient-therapist interaction to be complicated by sexual activity. Everyone strongly agreed on the unethical and destructive quality of sex between patient and therapist and the failure or inability of either patient or therapist to become aware of the transferential or countertransferential subtleties in such relationships. Nothing but a total injunction against such activity will encourage respect and trust in the treatment process.

The issue of training was also dealt with at the conference, and the need for adequate attitudinal growth as well as technical competence was stressed. The requisite background of the therapist depends on the nature and intensity of the sexual dysfunction. With minimal dysfunction, education or simple behavioral modification may suffice, but in the more extreme disorders, characterological inventories and biochemical studies may be required, necessitating sophisticated medical and psychological skills.

This was a trail-blazing conference and will surely be repeated at regular intervals. The report should be required reading for any practitioner who has the slightest brush with sexual problems in his or her practice.

LEON SALZMAN, M.D.
Washington, D.C.

Hero, Artist, Sage, or Saint? A Survey of Views on What Is Variously Called Mental Health, Normality, Maturity, Self-Actualization, and Human Fulfillment, *by Richard W. Coan. New York, N.Y., Columbia University Press, 1977, 316 pp., $20.00; $6.50 (paper).*

Professor Coan has written a scholarly, readable work that examines the evolution and elaboration of the basic ideas about the ideal person or the optimal personality. He examines such basic dichotomies in the traditions of Western thought as intellect versus emotions, individualism versus love, and materialism versus spiritualism, which we have inherited from such diverse sources as the ancient Greek philosophers, Christianity, the Renaissance, and the Enlightenment. He then reviews the ideas of the optimal person as found in the writings of the major figures in the history of modern psychology—Freud, Jung, Alder, Rank, and Fromm, to name just a few.

He presents a review of his own research, which involves a multivariate analysis of the optimal personality realm. He argues that all the ingredients of our concepts of the ideal condition can be reduced to five basic mode[illegible] fillment: 1) efficiency in the intellectual, soci[illegible] realm, 2) creativity, 3) inner harmony, a co[illegible] tioning of all parts of one's being, 4) relatedne[illegible] tion toward positive interaction with others, a[illegible] dence, the experienced dissolution of one's se[illegible] uality. His data and logical considerations po[illegible] of polarities in these categories, often neces[illegible] choice between mutually desirable but incom[illegible] All in all, we are in his debt for this schol[illegible] catholic presentation of the currents of th[illegible] have contributed to our ideas about what co[illegible] personality function.

FRANCIS J. K[illegible]
[illegible]

The Gay Academic, *edited by Louie Crew. [illegible] Calif., ETC Publications, 1978, 427 pp., $15.[illegible]*

This is a collection of essays by 27 men a[illegible] define themselves as "gay academics." Mo[illegible] them are members of college faculties, seve[illegible] students, and 3 are ordained members of [illegible] book is divided into 10 essentially disparat[illegible] ering general academic issues, history, libr[illegible] guistics, literature, philosophy, psychology, [illegible] ology, science, sociology, and political scie[illegible] According to the editor, the book "is intended as a sam[illegible] scholarship spawned in the Gay Liberation M[illegible] is often the case in collections of this kind, [illegible] quite uneven, and some of it is of very pa[illegible] such as the scholarly chapter presenting [illegible] Richard Burton's terminal essay in his transl[illegible] bian Nights or the short literary essay on Ha[illegible] the words "casque" and "cask" in several [illegible]

Some interesting differences in points of [illegible] gay liberation movement emerge in some of [illegible] Stanley contributes a rather shrill antim[illegible] ionated chapter (e.g., "If people could be [illegible] wanted to be, without the intense social co[illegible] would be lesbians and homosexuals") [illegible] cooperation between lesbians and homosex[illegible] several other essays emphasize the imp[illegible] working together for common goals. Edgar [illegible] tributes a charming and witty chapter in wh[illegible] things, he comments on the difficulties he ha[illegible] an advocate of the concept that male virgi[illegible] with a reasonably happy life. His "consis[illegible] est" in sex has been treated "as the unfo[illegible] homosexuals and heterosexuals alike. [illegible] France's comment that "chastity is the [illegible] versions," Friedenberg observes wryly, "[illegible] takes all kinds, doesn't it?"

Perhaps the most interesting chapter (fo[illegible] Crampton's moving and scholarly essay on [illegible] from Leviticus to Hitler" documenting the [illegible] homosexuals have been brutalized and murd[illegible] ancient Hebrews around 550 B.C. and the[illegible] later with Christianity's coming to powe[illegible] rope. Genocidal laws against homosexuals [illegible] criminal codes of France until 1791, of En[illegible] and of Scotland as late as 1889. Both male a[illegible] sexuals were subject to capital punishmen[illegible] the American colonies, but the death penal[illegible]

revoked after the Revolution. The most recent episode of gay genocide cited by Crompton was in Hitler's Germany, when more than 50,000 homosexuals in Germany alone were arrested and sent to perish in concentration camps. When those seized by the Nazis in occupied countries are added, estimates of the number of homosexuals who died "from illness, neglect, medical experiments, and the gas chamber" range from 100,000 to more than 400,000.

The section on psychology contains only two chapters, one by De Cecco and Shively on "Conflicts Over Rights and Needs in Homosexual Relationships," and the other by Mark Freedman (now deceased) on "Toward a Gay Psychology." The former deals with some of the conflicts encountered in homosexual relationships and the use of negotiation as a way of ensuring the democratic rights of the individuals concerned. Freedman's article claims that there are "at least four major areas in which gays often function better than nongays." He defines these as 1) inner direction/centering (discovering and living by their own values), 2) sex roles (a wider range), 3) sexuality (more openness, sensuality, and freedom), and 4) identity/self-disclosure (more candidness and less defensiveness, at least among homosexuals who have "come out"). He concludes with the hope that out of the experience of emerging gay groups a special gay psychology will develop that will contribute to a better understanding of the gay community.

In summary, *The Gay Academic* is a potpourri of uneven quality. With the exception of a handful of chapters, it will be of only moderate interest to most psychiatrists.

JUDD MARMOR, M.D.
Los Angeles, Calif.

The Family Crucible, *by Augustus Y. Napier, Ph.D., with Carl A. Whitaker, M.D. New York, N.Y., Harper & Row, 1978, 293 pp., $11.95.*

This book is a delightfully novel way of presenting family therapy—novel in several senses of the word. Augustus Napier has devised a new method admirably suited for his intended purpose of capturing the "feel" of family therapy carried out with Carl Whitaker. With literary skill and psychological sophistication, Napier has made real the therapy with one family; the actual dialogue and episodes are a composite from several families, selected to illustrate the processes of the Whitaker approach to family therapy. Paragraphs and chapters on basic concepts, theory, and methods of family therapy clarify and highlight but do not disrupt the absorbing tale of the primary family. In my view, the fictionalized narrative succeeds in providing a more accurate portrayal of family therapy with Whitaker and Napier than could a factual account of any single, inevitably atypical case. This narrative is far more readable and vivid than would be a bare-bones presentation of abstract or technical principles.

Although Whitaker's personal qualities as a family therapist are widely known through his many presentations at workshops and symposia, his emphasis on growth through personal struggle is greatly illuminated by the longitudinal view of this case description. This presentation makes room for describing the context and timing of his therapeutic interventions and hence should help make the rationale of his "experiential" approach more accurately understood than is possible from vignettes.

Whitaker's therapy is marvelously packed with dilemmas and paradox. On the one hand, he draws unabashedly on the power accorded the grandfatherly old-time physician in order to win the initial "battle for structure" in the therapeutic relationship. On the other hand, having provided the security of this framework, he respectfully waits for the family to take the initiative and responsibility in accord with their readiness and ability to begin to change. While exerting great personal strength and firmness, he relies on a cotherapist relationship to free himself—and the family—for expressions of fantasy, warmth, and what he disarmingly calls "craziness."

In the cotherapy described here, both Whitaker and Napier make contributions that are independent but complementary, distinctive but supportive. Unlike most present-day psychotherapists, Whitaker and Napier maintain an interest in both intrapersonal and interpersonal levels of functioning, both of the individual as a person and the family as a system. While focusing on the immediate experience in the therapy itself, the authors bring to life a historical perspective toward transgenerational origins, for example, through direct "consultations" with families of origin. Most valuably, this narrative gives a sense of therapy as a process with phases, moving in a spiral course from family unit to individual, from one person to another, from present to past, and from playful good humor to surges of violent intensity.

Professional readers need to be warned that this volume misleadingly appears to be addressed to the general public. It differs from our usual publications in that it is highly absorbing and readable. It also explicitly discusses the gains and hazards of family therapy from the perspective of family members, who are given an inside look at the difficult, complex, and sometimes scary process. Nonetheless, I hope that clinicians of diverse persuasions will enter into this book and may glimpse the special gains that await therapists who take the risks of engaging themselves in this approach to family therapy.

LYMAN C. WYNNE, M.D., PH.D.
Rochester, N.Y.

A Reassessment of the Concept of Criminality: An Analysis of Criminal Behavior in Terms of Individual and Current Environment Interaction. The Application of a Stochastic Model, *by Eggert Petersen. Copenhagen, Denmark, Munksgaard (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1977, 134 pp., $32.50.*

There is an inclination to deplore evidences of increasing criminality today. In the main, this evidence consists of reports of conventional offense rates, which are derived from counts of the number of offenses occurring within a specified area during a stipulated period, measured against the estimated number of residents of the area, usually obtained from standard census data. Leaving aside questions concerning the validity of such data, it should be clear they have limited usefulness in the development and/or assessment of theories of criminality, although they are often used to support the contention that the criminal justice system is not very effective in modifying or controlling criminality.

This scholarly study of criminality among men in the Danish Navy hypothesizes that criminality does not characterize the individual but is, rather, the effect of interaction between the individual and his environment. To test his thesis, Petersen examines criminality against the backdrop of the military society and the special characteristics and aims of its judicial

system. On the basis of a comprehensive review of past studies of criminality in the military, he draws the interesting conclusion that "military criminologists in general seem to regard military criminality as a phenomenon characterizing the criminal individual per se."

In his search for a more dynamic understanding of criminality, the author analyzed data relating to sanctions, service records, results of military psychological tests, biographical data, job satisfaction inventories, and the characteristics of service posts. Within these parameters, the investigation focused on a large number of variables relating to individual servicemen and the service posts to which they were assigned. The job satisfaction inventory that the author devised deserves special recognition as a device for the measurement of individual attitudes.

In his analysis of factors in the individual and in his service posts that might predispose to criminality, the author concludes that

> there is no single factor at the bottom of naval criminality, nor only a complex of personal factors, but there is an interaction between person and service post which it has proved possible to describe by means of a probability model, which comprises a person parameter (sanction pronity) and a service post parameter (sanctioning inclination) that both vary greatly.

In the last chapter, the author makes some practical suggestions for combating naval criminality, mainly in the area of improving job satisfaction at various service posts.

This monograph is recommended as a model for multifactorial investigation into the basis for criminality. No doubt it has implications for the study of other behavioral phenomena as well.

CHARLES E. SMITH, M.D.
Chapel Hill, N.C.

Drug Abuse in Pregnancy and Neonatal Effects, *edited by José Luis Rementeria, M.D. Saint Louis, Mo., C.V. Mosby Co., 1977, 284 pp., $18.95.*

This is a valuable and welcome book. It is a comprehensive overview of current knowledge concerning the effects of a number of drugs of abuse on the developing fetus and on the neonate. Its primary appeal and value will be to the obstetrician and neonatologist working with pregnant addicts and other drug abusers. Other medical and paramedical personnel working with substance abusers will also find the answers to their own and their clients' questions about the effect of a variety of abused substances on the fetus and newborn in this volume.

Although it is a useful compendium, it has its weaknesses. It is an edited volume, with individual chapters authored by experts. Like many such volumes it suffers from a lack of tight editorial control. It is repetitious, and some chapters could have been combined. For example, chapter 21, "Disposition and Planning Long-Term Follow-Up of the Infant After Release from the Hospital," and chapter 23, "Social Agencies and Their Role in Working with the Infant and Family," go over similar material with only a slight difference in perspective.

There are divergent opinions between authors, and in some instances the editor highlights these, but in other instances the contradictions are neither pointed our nor resolved. Thus one cannot browse through this v... sult a single chapter and be sure that he or she ... authoritative viewpoint. In chapter 3 there is ... omission under cardiac complications. Alth... endocarditis as a complication of heroin abus... no mention is made of fungal endocarditis. Ad... a rare finding, but it is well-known and ar... limited to mainlining heroin addicts. It is imp... it is frequently overlooked and the appropri... procedures are not ordered.

Finally, it would have added to the value o... editor had provided a summary chapter for ... major sections. Such a synthesis would have ... hicle for dealing with contradictory material ... provided a welcome overview of the relat ve ... the findings of the individual authors, mak... more valuable reference.

Studies of the Effectiveness of Treatments fo... Vol. V: Evaluation of Treatment Outcomes ... DARP Admission Cohort, *edited by S.B. ... Dwayne Simpson. Cambridge, Mass., Ballin... Co. (J.B. Lippincott Co.), 1976, 512 pp., $25...*

This volume is the fifth research study de... the Drug Abuse Reporting Program (DARP) on th... treatment for drug dependence by the staff of ... Behavioral Research of Texas Christian Univ... porting program was established by NIMH... studied include 43,943 admissions to 52 feder... treatment agencies from June 1, 1969, thro... 1973, and followed for the fifth year. The ... books in this series studied the admissions ... present volume reports on the 16,000 adm... 1973.

The chapters in each of the six parts of the ... the segments of the research, including the ... treatment, death rates, causes of death for ... and the validation of drug abuse treatment ... amplify work on methadone maintenance, th... munities, outpatient drug-free therapy, and ...

The researchers, using quite complex an... recorded the multiple studies in great deta... samples of patients. The results demonstr... who remained in treatment tended to show p... "no clear cut superiority of any one treatm... any modality was found for all types of pa... adone maintenance showed the best during-tr... ioral outcome record in reducing opioid use ... and increasing employment and productive ... other finding was that "all treatments ... tients in a therapeutic setting for the intende... ration and completion." In striving to anal... authors admit that sometimes "more questi... than were answered."

A good section of this volume from the v... clinical psychiatrist is the study of death rate... death for opiate addicts in treatment. The ov... was 13 per 1,000, with violence and factors ... use contributing to 72% of the deaths. Anoth... tion deals with a method for the classificatio... treatment programs on the basis of scoring ...

an attempt to establish an evaluation technique that can be useful for future research.

All in all, this book is not easy for the clinical psychiatrist to digest. It is lengthy, difficult to follow at times because of the overuse of acronyms, and full of tables (I counted 156); it also places much emphasis on the details of procedures, most of which are geared to the researcher.

MANUEL M. PEARSON, M.D.
Philadelphia, Pa.

Handbook of Physiology: A Critical, Comprehensive Presentation of Physiological Knowledge and Concepts, Section 1: The Nervous System. Vol. I: Cellular Biology of Neurons, Parts 1 and 2, *edited by John M. Brookhart and Vernon B. Mountcastle; Eric R. Kandel, volume editor; Stephen R. Geiger, executive editor. Baltimore, Md., American Physiological Society (Williams & Wilkins Co., distributor), 1977, 1,182 pp., $135.00.*

These two books provide a systematic introduction to the functioning of nerve cells that will be invaluable as a reference work for the graduate student and the scientist who is interested in a modern review of ongoing research in cellular neurobiology. The volumes are not meant for or applicable to the casual reader interested in a review of new knowledge in cell biology of neurons.

The important new findings described in these volumes include the analysis of fine structure of the neuron, further progress in understanding the excitation and conduction in neurons, and the recent findings in synaptic transmission. Perhaps of most importance to psychiatry are the applications of techniques of cell biology to the study of systems of neurons. It is hoped that such studies might lead to an understanding of how the sensory and motor systems are organized and how the neuronal circuits of behavior are modified by learning.

The two parts of volume 1 are an unsurpassed systematic introduction to functioning of nerve cells. They should be available to serious students of the nervous system.

DONALD W. MULDER, M.D.
Rochester, Minn.

Medicolegal Aspects of Hospital Records, 2nd ed., *by Emanuel Hayt, LL.B. Berwyn, Ill., Physicians' Record Co., 1977, 506 pp., $19.80.*

This is a good book, presenting a complicated subject in a systematic and understandable manner. It can be a useful guide for medical records librarians, hospital administrators, and physicians as long as the reader keeps in mind that "no book can be a substitute for competent legal advice" (p. xii).

It covers much more than its title implies. It shows the reader how a lawyer reads and interprets a medical record and how points that medically trained people may consider trivial can come to haunt them if not properly attended to. It provides a guide to courtroom procedures and illustrates the various situations in which medical and other hospital records are used in and by the courts. The systematic presentation and comprehensive discussion of the records hospitals are required to keep are made more interesting and understandable through examples from actual cases decided in the courts. Another important aspect of the book is that it incorporates the requirements of the Joint Commission on Accreditation of Hospitals.

On the negative side, the book was written for use in general hospitals and makes only a few references to situations peculiar to psychiatric institutions. The recently adopted statute dealing with the confidentiality of medical records of alcoholic and drug addicted patients is not included. Although the table of contents is exhaustive, the index leaves a lot to be desired.

MARIJAN HERJANIC, M.D.
St. Louis, Mo.

Handbook of Studies on Depression, *edited by Graham D. Burrows. Amsterdam, the Netherlands, Excerpta Medica (Elsevier/North-Holland Biomedical Press), 1977, 420 pp., $68.00.*

Norman Sartorius, Director of the World Health Organization's Division of Mental Health, has stated that epidemiological surveys have disclosed that on any given day there are one hundred million people with clinically recognizable and treatable depression. He also forecasted that in the next decade there will be a substantial rise in the incidence of this affective disorder. It is not surprising, therefore, that physicians, especially psychiatrists, have become more eager to learn more about depression and its treatment and that the number of books devoted to the etiology, biochemistry, manifestations, and treatment of depression has escalated in the past few years.

This well edited book is the latest and one of the best of the multidisciplinary treatises on depression. It is divided into four sections: the first is devoted to classification, phenomenology, and etiology; the second to treatments; the third to current research; and the last to bereavement, suicide, cardiac effects of tricyclic antidepressants, and the management of drug overdose.

The contributors to this volume are acknowledged international authorities. Each lucidly, concisely, and comprehensively covers his or her area of expertise. The result is a very readable book with a wealth of up-to-date information on all aspects of depression. Having read many of the recent books on depression, I can forthrightly state that, although expensive, this volume offers the reader so much data to increase his or her knowledge of the illness and its therapies, it will be judged a worthwhile investment.

FRANK J. AYD, JR., M.D.
Baltimore, Md.

Psychiatric Diagnosis. The C.M. Hincks Memorial Lectures, *edited by Vivian M. Rakoff, M.A., M.B.B.S., Harvey C. Stancer, Ph.D., M.D., and Henry B. Kedward, M.A., M.D. New York, N.Y., Brunner/Mazel, 1977, 228 pp., $15.00.*

Psychiatric Diagnosis consists of nine papers written by different authors. Reading these consecutively makes one aware of a level of difficulty beyond that considered in each paper; namely, how can the approaches be reconciled? Drs. Spitzer, Sheehy, and Endicott present a clear outline of the multiaxial diagnostic system of *DSM-III*. Dr. Stoller, discussing psychodynamic diagnoses, points out that a diagnostic system which neglects the meaning of a symptom to the

patient is incomplete. Dr. Reitan provides an excellent review of the utility of neuropsychological concepts and testing. He demonstrates that cerebral lesions can give distinct syndromes influencing behavior and that the diagnosis of organic brain syndrome, as conventionally used, cannot describe the multiplicity of specific deficits that may occur.

Dr. Roy Grinker, Sr., describes the necessity of making diagnoses that reflect all available and pertinent data. Dr. Wing's article includes so many issues that it is in itself the basis for a book. A noteworthy concept is that of basing all diagnoses (including multiaxial diagnoses) on objective or at least overt clinical findings; a system for doing so is described. Dr. Wender reviews the concept of a schizophrenic spectrum. He is not evasive in defining often ill-defined terms, such as chronic schizophrenia, borderline schizophrenia, "reactive" schizophrenia, "schizoid" phenomena, and dementia praecox.

Dr. Winokur provides a review of the genetic determination of major affective disorders, the separation between unipolar and bipolar disorders, and the likely existence of two types of unipolar depression. He also gives a concise review of genetic markers for affective disorders. Dr. Van Praag presents the need for making diagnoses in terms of differentiation of biological substrates, particularly in relation to catechol and indole metabolism when defining affective disorder. This dimension, as outlined, is independent of etiology, symptoms, and prognosis. Dr. Feinstein, an internist and epidemiologist, gives an elegant summary of the various patterns of inference applied to available evidence in diagnostic procedures.

The quality of the individual articles is good. Each remains in its area rather than becoming global or criticizing other systems. The articles on neuropsychological deficit, the schizophrenic spectrum, and genetic patterns in affective disorder will be of direct interest to clinicians. This book demonstrates that adequate psychiatric diagnosis requires descriptions in several frameworks and gives the term "multiaxial" meaning and relevance.

MARTIN H. KEELER, M.D.
Houston, Tex.

Religious Encounters with Death: Insights from the History and Anthropology of Religions, *edited by Frank E. Reynolds and Earle H. Waugh. University Park, Pa., Pennsylvania State University Press, 1977, 244 pp., $14.50.*

In view of the current popularity of books dealing with various aspects of death and the dying process, this volume of essays from ethnographic and historical viewpoints is most welcome. The book is primarily the outgrowth of papers presented at the 1973 convention of the American Academy of Religion. Eleven of the 15 essays are based on papers presented at that meeting. The original papers were modified to make the scholarly material more accessible to the nonspecialist reader.

The editors' introduction gives coherence to the essays by considering death in terms of "disjunction, continuity, transition, integration, and transformation." They make the valuable point that although varying cultures produce a "dazzling array of differences," there is an "undeniable core of unity" in the way people deal with death.

Two comparative studies begin the collect[ion] by Mircea Eliade, gives an arresting and helpfu[l] sketch of underlying mythologies of death. [The] paper on death and pilgrimage seemed less [rel]evant to the general topic. The remaining papers concern [...] death in various cultural traditions. Benjamin [...] "Death, Kingship and Royal Ancestors in [...] onstrates the real archetypal connection of [...] royal forebears as a major source of General [...] er. Franke Neumann's paper on the gatekee[per] tures vividly the spiritual tribulations and [...] death of Moctezuma II (Montezuma) at the [...] empire.

The first of the 4 essays on Indian religion[s], Long, describes the way in which Vedic and [...] duism dealt theistically and nontheistically [with] questions concerning human mortality. David [...] ticle on medieval Hinduism presents an [...] cussion of the conquering of death and the [...] al rebirth by fantasying and meditating in [...] death. The enormously elaborate rituals [...] ent-day Hindu families to assure their [...] place in heaven are depicted in David Knipe's [...] Pangborn outlines the Parsis' death rituals [...] connects their death anxiety to the anxiety [...] gard to their probably dying culture. In [...] Shōsan's samurai and Zen death techniques [...] gives a lively account of a samurai warrior [...] who attempted to live in a state of "perpetual [...] of his own death."

Those of us reared in the Western tradition[s] God will feel on more familiar ground in the [...] Judaism. Wolfrom Herrmann considers the [...] mortality as it is described in the Old Testament [...] dilemma of meeting death and yet not actual[ly] movingly portrayed by Pesach Schindler in [...] the Polish Hasidim during the Holocaust.

In the section on Islam, Alford Welch sum[marizes] jor points in the Koran on death and dying [...] some of the Koran's death symbolism with sl[ight] in Shī'a communities and their relevance [for] the terror of death for community members [...] validate the history of this minority Islamic [...] cussed by Earle Waugh.

Glen Davidson's contribution presents inte[resting] on death in three seventeenth-century N[ew] groups—the Huron Indians, the Catholic [...] Puritan New Englanders, but his conceptua[l] forced. In his essay on Lincoln's assass[ination] Capps explicates a tragic mythic dimension o[f] presidency and considers the effect of the [...] frontier mythology.

In general, I found the essays in this book [...] well written except for some undefined terms [...] tion of different cultural attitudes and ri[tuals] death is lucidly set forth. I think that *Religi[ous] with Death* can fulfill the editors' aim of help[ing] develop a "personal 'language' of death." [For] therapist this volume can be additionally val[uable] him or her understand patients in their [...] mortality in themselves and others.

Just Published . . .

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

The practical calculations of antidepressant therapy

÷

Divide scored Endep tablets

+

Add flexibility to dosage titration

Long term treatment of depression with amitriptyline requires precise calculation of dosage to meet the individual needs of each patient. Because all six strengths of Endep are scored, you can easily increase or decrease dosage in half-tablet steps, without the bother and expense of a new prescription.

−

Subtract waste and cost

Scored Endep tablets permit you to adjust the regimen without wasting unused tablets or burdening the patient with the cost of a new prescription.

×

Multiply therapeutic options

The pharmacokinetic properties of Endep are such that its clinical effect is the same whether prescribed *t.i.d.* or as a single daily dose. Thus, once you have established the proper dosage, you can prescribe the entire dose *h.s.*, minimizing anticholinergic and sedative side effects, and helping to assure patient compliance with this simple regimen.

By prescribing the higher strength tablets *h.s.*— secure in the knowledge that the dosage can be adjusted without resorting to a new prescription—your patient will economize further on a per milligram basis.

Endep®

amitriptyline HCl/Roche

The only antidepressant scored for easy division

Endep
amitriptyline HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Supplied: *Scored Tablets:* 10, 25, 50, 75, 100, 150 mg.

Haldol®
(haloperidol)
tablets/concentrate/injection

Promptly controls psychotic symptoms... usually leaving the patient alert and productive

Highly effective in a wide range of both acute and chronic psychotic disorders,[1-7] such as hallucinations, delusions, suspiciousness, hostility, mania.

Permits aggressive titration to effective dosage levels for optimal response.[1,4]

Facilitates prompt initiation of other therapeutic efforts... and often helps avoid hospitalization.[1-3]

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects.[2,4-6,8,9] Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Common side effects easily controlled.[1,2,4-7] Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

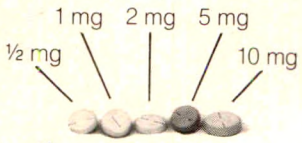
*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Please turn page for summary of prescribing information.

concentrate

A tasteless, odorless, colorless liquid concentrate for better patient compliance: 2 mg per ml.



injection

A rapid-acting injection for psychiatric emergencies: 5 mg per ml,* with 1.8 mg methylparaben and 0.2 mg propylparaben per ml, and lactic acid for pH adjustment to 3.4 ± 0.2.

tablets

5 tablet strengths for convenience in individualizing dosage:

HALDOL® (haloperidol)

tablets/concentrate/injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.

MSD
MERCK SHARP & DOHME

widely useful in psychiatric practice
when moderate anxiety
or agitation accompanies depression

dual-action Triavil®

containing perphenazine and amitriptyline HCl

prescribe it...
with good reason

For a brief summary of prescribing information, please see last page of this advertisement.

widely useful in psychiatric practice when moderate anxiety or agitation accompanies depression

Helps treat the total symptom complex—moderate anxiety and coexisting depression.

The antidepressant component is capable of alleviating such symptoms of depression as early morning awakening, anorexia, poor concentration, and feeling of hopelessness.

The tranquilizer component is capable of alleviating symptoms of anxiety, tension, and psychomotor excitement without apparent dulling of mental acuity. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active.

The drug may impair mental and/or physical abilities required for performance of hazardous tasks such as operating machinery or driving.

Depending on the condition being treated, relief of symptoms of anxiety may occur within a few days, but adequate relief of symptoms of depression may take a few weeks or even longer.

Symptomatic relief often increases the patient's ability to return to normal family, social, and vocational activities.

Flexibility of four tablet strengths affords ease of dosage adjustment for better patient management.

Initial therapy for many patients is TRIAVIL® 2-25, containing 2 mg perphenazine and 25 mg amitriptyline HCl, or TRIAVIL® 4-25, containing 4 mg perphenazine and 25 mg amitriptyline HCl, t.i.d. or q.i.d. See full prescribing information for dosage in elderly and adolescent patients.

Treatment with TRIAVIL—a balanced view: TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

a wide range of indications...

patients with moderate to severe anxiety and/or agitation and depressed mood

patients with depression in whom anxiety and/or agitation are severe

patients with depression and anxiety in association with chronic physical disease

schizophrenic patients who have associated depressive symptoms

dual-action TRIAVIL®

containing perphenazine and amitriptyline HCl

prescribe it... with good reason

widely useful in psychiatric practice when moderate anxiety or agitation accompanies depression

dual-action Triavil®

containing perphenazine and amitriptyline HCl

prescribe it...with good reason

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered. Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Associat

This book reports six studies that add to the growing body of data demonstrating the feasi ering mental illness under health insurance. Although in some ways it may be considered a s APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND** Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal emp menting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health b
- Coverage of mental illness under collective bargaining agreements of selected union
- Utilization of care for mental conditions under the Canadian health insurance program the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of tions, with emphasis on major medical coverage.

One way to evaluate seizure etiology

Computerized transaxial tomography (CT scan) is an important new noninvasive technique that can help in determining the etiology of epileptic seizures. Shown here is a single slice from a color-enhanced CT scan of the brain of a patient with epilepsy. The absence of vascular abnormalities, tumor, or other lesions is compatible with a diagnosis of idiopathic epilepsy.

A proven way to start seizure control

MYSOLINE®
(primidone) Tablets 50 mg, 250 mg Suspension 250 mg/5 ml

A single entity with multiple anticonvulsant properties

Primidone itself has anticonvulsant activity. In addition, its major metabolite, phenylethylmalonamide (PEMA), exerts an anticonvulsant effect of its own and also enhances the anticonvulsant action of the second metabolite, phenobarbital. In patients refractory to phenytoin and phenobarbital, primidone may prove effective as the sole therapy.[1]

Multiple indications—grand mal, psychomotor, and focal epileptic seizures

In grand mal, MYSOLINE is comparable in efficacy to phenytoin and phenobarbital.[2,3] In psychomotor seizures, phenobarbital is rarely effective.[1] In focal seizures, phenytoin used alone is not indicated[4]—and, according to Forster,[3] MYSOLINE is markedly more effective than phenobarbital, which should dispel the misconception that MYSOLINE is "just a phenobarbital." (See chart below.)

Efficacy ratings* of anticonvulsants in epilepsy

Agent	Grand Mal	Psychomotor	Focal
Mysoline	++++	++++	++++
Hydantoinates (phenytoin)	++++	+++	+++
Barbiturates (phenobarbital)	++	++	++

*Relative effectiveness, ++++ being most effective.
Adapted from Forster, F. M.[3]

Consider it first for major motor epilepsies

MYSOLINE® (primidone) Ayerst®

See next page for Brief Summary and references.

Start seizure control with MYSOLINE® (primidone)

Initial dose in children over 8 years of age and adults: 250 mg daily at bedtime

BRIEF SUMMARY
(For full prescribing information, see package circular.)
MYSOLINE®
Brand of **PRIMIDONE** *Anticonvulsant*

ACTIONS: MYSOLINE raises electro- or chemoshock seizure thresholds or alters seizure patterns in experimental animals. The mechanism(s) of primidone's antiepileptic action is not known.

Primidone *per se* has anticonvulsant activity as do its two metabolites, phenobarbital and phenylethylmalonamide (PEMA). In addition to its anticonvulsant activity, PEMA potentiates that of phenobarbital in experimental animals.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several weeks before it can be assessed.

Usage in pregnancy: The effects of MYSOLINE in human pregnancy and nursing infants are unknown.

Recent reports suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Data are more extensive with respect to diphenylhydantoin and phenobarbital, but these are also the most commonly prescribed anticonvulsants; less systematic or anecdotal reports suggest a possible similar association with the use of all known anticonvulsant drugs.

The reports suggesting an elevated incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodologic problems in obtaining adequate data on drug teratogenicity in humans; the possibility also exists that other factors, *e.g.*, genetic factors or the epileptic condition itself, may be more important than drug therapy in leading to birth defects. The great majority of mothers on anticonvulsant medication deliver normal infants. It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

PRECAUTIONS: The total daily dosage should not exceed 2 g. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 g per day. The initial dose is 250 mg. Increments of 250 mg are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 g. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg daily at bedtime	*2nd Week* 250 mg b.i.d.
3rd Week 250 mg t.i.d.	*4th Week* 250 mg q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg, with gradual weekly increases of 125 mg a day, to a daily total usually between 500 mg and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE Tablets—No. 430—Each tablet contains 250 mg of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg of primidone (scored), in bottles of 100 and 500.
MYSOLINE Suspension—No. 3850—Each 5 ml (teaspoonful) contains 250 mg of primidone, in bottles of 8 fluidounces.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Awake on the job...

yet anxiety controlled

Troublesome drowsiness uncommon

Tranxene lets you manage anxiety in most patients without problem sedation. Any initial drowsiness is usually transient.

Calming without impairment

Patients not oversedated can function better on the job* or at home. By avoiding excessive sedation, Tranxene helps you calm patients without compromising their capacities.

*Of course patients should be cautioned against hazardous tasks requiring mental alertness. See overleaf for prescribing information.

8073255

Tranxene® (CLORAZEPATE DIPOTASSIUM) 4306CB

CAPSULES,
SINGLE DOSE TABLETS

Brief Summary

ABBOTT

ACTIONS — Pharmacologically, clorazepate dipotassium has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine. (See CLINICAL PHARMACOLOGY section.)

INDICATIONS — TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS — TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS — TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS — In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS — The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION

For the symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For the symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg. TRANXENE initially, followed by 30 to 60 mg. in divided doses; 2nd 24 hours, 45 to 90 mg. in divided doses; 3rd 24 hours, 22.5 to 45 mg. in divided doses; 4th day, 15 to 30 mg. in divided doses. Thereafter gradually reduce to 7.5 to 15 mg. daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS — If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE — Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE (clorazepate dipotassium) as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY — Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption — Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

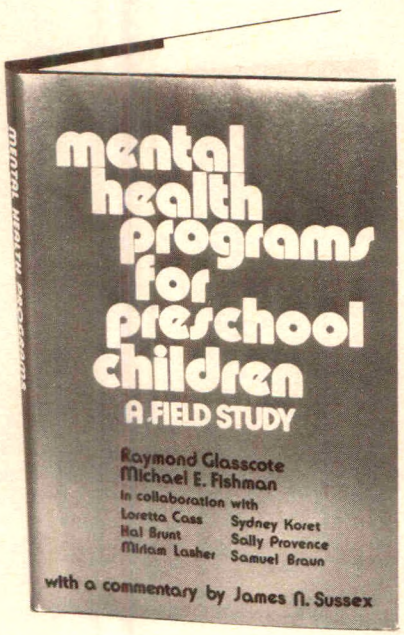
HOW SUPPLIED — TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 30 (NDC 0074-3418-30), 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:



TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 30 (NDC 0074-2699-30) and 100 (NDC 0074-2699-13).

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.

Some antidepressants have specific daytime benefits.

PAMELOR®

(nortriptyline HCl)NF

25 mg. Capsules

has them both.

Some antidepressants have specific nighttime benefits.

- Sleep patterns begin to improve within a week.
- Patients feel calm, yet remain alert.

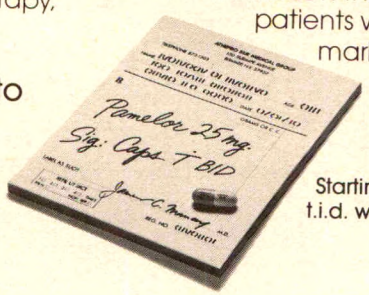
For Brief Summary please see following page

SANDOZ PHARMACEUTICALS
East Hanover, N.J. 07936

PAMELOR®
(nortriptyline HCl)NF
25 mg. Capsules

The antidepressant with both daytime and nighttime advantages.

PAMELOR® therapy begins to improve sleep patterns within a week.



- PAMELOR therapy helps relieve the sleep problems that accompany depression: difficulty in falling asleep, restless sleep, and early-morning awakening. An improved pattern of sleep begins to appear in some patients within the first week of therapy.
- Overall improvement is often observed by the end of the second week. Maximum improvement with PAMELOR therapy, as with other antidepressants, may require a longer period of therapy, particularly in severe depressive illnesses.

PAMELOR therapy allows patients to remain calm yet alert.

- Helps improve depressed mood with a low level of stimulatory effect.
- PAMELOR therapy also has a mild calming action to help relieve the anxiety and tension that are often symptoms of depression. Because PAMELOR therapy rarely causes excessive drowsiness, patients are more alert and better able to function. Nevertheless, they should be cautioned about driving or operating machinery.

PAMELOR therapy is well tolerated.

- In 90 studies in which 818 patients were treated with PAMELOR therapy, over half (54%) of the patients who improved completely or markedly had no side effects at all.

Starting dosage 25 mg. b.i.d. Increase to 25 mg. t.i.d. within the first week as required.

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Dosage and Administration: *Usual adult dose*—25 mg. three or four times daily; dosage should begin at a low level and increase as required. *Elderly and Adolescent*—30 to 50 mg. per day, in divided doses. Doses above 100 mg. per day and use in children are not recommended. If a patient develops minor side effects, the dosage should be reduced. The drug should be discontinued promptly if adverse effects of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution 10 mg./5 cc.

They're Fighting for His Life.

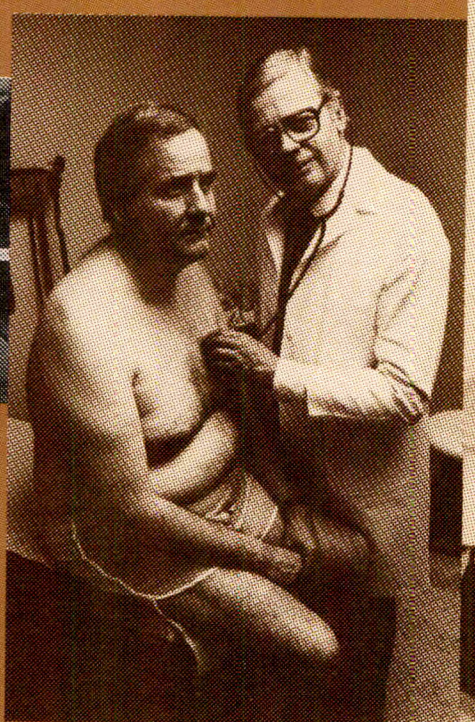
Each year heart attack accounts for over 350,000 deaths which occur before the victim reaches the hospital. It doesn't have to be that way.

What is done for a victim within the first few minutes after a heart attack may determine survival or death. Cardiopulmonary resuscitation (CPR) could make the difference. And you can learn it.

Some day, with CPR, you could save a life. Some day, your own life could depend on it.

CPR is a basic life-saving technique, performed after a person has suffered "cardiac arrest" — that is, after the heart has stopped beating. It provides emergency life support until more advanced support is available, through a combination of chest compression and mouth-to-mouth breathing.

Trained instructors, certified by the American Heart Association, can teach you CPR. It takes several hours. It could mean a lifetime.

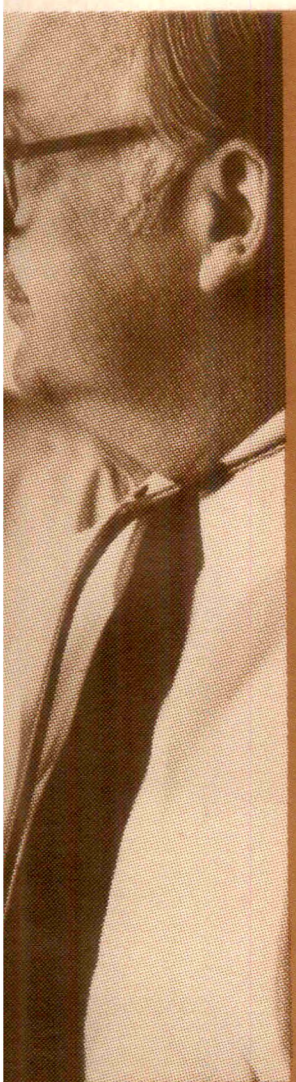


Contact your local Heart Association for more information on this program.

The American Heart Association

WE'RE FIGHTING FOR YOUR LIFE

Librium®... an unsurpassed
(chlordiazepoxide HCl)



More than two decades of research—including hundreds of animal studies and hundreds of clinical trials—stand behind the proven antianxiety performance of Librium.

ROCHE

safety record

What excited clinical researchers about Librium was its promise of effective antianxiety action within an unprecedented margin of safety. This promise continues to be fulfilled in millions of patients today— most likely including many of your own.

The highly favorable benefits-to-risk ratio of Librium is a well-documented matter of record. Clinical experience with millions of patients indicates that the most common side effects are dose-related and thus largely avoidable. Tolerance rarely develops at recommended doses. Few cases of known toxicity have been reported. In proper dosage, Librium rarely interferes with mental acuity or produces adverse effects on the cardiovascular or respiratory system. Patients should, however, be cautioned about performing tasks requiring mental alertness, such as driving, and possible combined effects with alcohol.

- ☐ Proven antianxiety performance
- ☐ Minimal effect on mental acuity
- ☐ Predictable patient response
- ☐ Is used concomitantly with primary medications, such as anticholinergics and cardiovascular drugs

Librium® (IV)

chlordiazepoxide HCl/Roche

5mg, 10mg, 25mg capsules

synonymous with relief of anxiety

Please see next page for summary of product information.

Librium® 5mg, 10mg, 25mg capsules
chlordiazepoxide HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states. Efficacy beyond four months not established by systematic clinical studies. Periodic reassessment of therapy recommended.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Warn patients that mental and/or physical abilities required for tasks such as driving or operating machinery may be impaired, as may be mental alertness in children, and that concomitant use with alcohol or CNS depressants may have an additive effect. Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral–Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10. Libritabs® (chlordiazepoxide) *Tablets*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

PLAN AHEAD!!!
Order your 1979 Appointment Book Now !!!

The "week-at-a-glance" Appointment Book, published by the American Psychiatric Association, has been developed over several years to satisfy the needs of as many members as possible. It contains a comprehensive list of addresses and annual meeting dates of all major organizations and agencies of interest to psychiatrists. Members who have not tried this book in the past are urged to do so. It is returnable within 30 days for a full refund if not acceptable. In addition, the name of the physician or hospital can be imprinted on the front cover for $1.00 a copy, providing that the order is received by July 15.

The Pocket Size Appointment Book is also available and can be ordered in combination with the Desk Appointment Book.

Copies will be available September 1978

DESK: $10.00
POCKET: $6.00
BOTH: $15.00
10% Discount for 10-99 copies
15% Discount for 100 copies or more

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

"I'm just a shadow of what I used to be."

That is what depressed individuals may feel is the substance of their being. There is no pleasure, no joy – nothing grows – and in the cold shadow of depression their activities are inhibited, while initiative may be eroded or destroyed. The tragedy is that they can see that others are able to live on the brighter side but they, themselves, cannot reach it on their own.

Your experience in treating depression, and Tofranil-**PM** can help light the way.

Tofranil-**PM**®
imipramine **pamoate**

Geigy

Unsurpassed effectiveness among tricyclics in relieving symptoms of anxious depression.

Before prescribing Tofranil-PM, please review a summary of the prescribing information on the back of this page.

Tofranil-PM®
imipramine **pamoate**

Geigy

As anxiety, agitation, sleep disturbances, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

Everybody knows somebody who's been helped.

The United Way is reaching out. It goes into every neighborhood. To every age group. Across every income level.
To help. In a thousand ways.
A neighbor. A relative. Maybe someone down the street who's out of work. Or sick. Or in trouble.
Chances are the United Way helps someone you know.
Maybe someday it'll be helping you.

Thanks to you it works . . .

Prescribing Information for

Lidone™ (molindone hydrochloride)

DESCRIPTION — LIDONE (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

LIDONE is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4(5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

ACTIONS — LIDONE (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, LIDONE antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, LIDONE exerts its effect on the ascending reticular activating system.

Human metabolic studies show LIDONE (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24 to 36 hours. There are 36 recognized metabolites with less than 2 to 3% unmetabolized LIDONE being excreted in urine and feces.

INDICATIONS — LIDONE (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS — LIDONE (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats Oral Dose —
20 mg/kg/day — 10 days, no adverse effect
40 mg/kg/day — 10 days, no adverse effect

Pregnant Mice Oral Dose —
20 mg/kg/day — 10 days, slight increase resorptions
40 mg/kg/day — 10 days, slight increase resorptions

Pregnant Rabbits Oral Dose —
5 mg/kg/day — 12 days, no adverse effect
10 mg/kg/day — 12 days, no adverse effect
20 mg/kg/day — 12 days, no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of LIDONE (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of LIDONE (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS — Some patients receiving LIDONE (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving LIDONE. Caution should be exercised where increased activity may be harmful.

LIDONE does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

LIDONE has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS

CNS Effects — The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological Extrapyramidal Reactions — Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia — Motor restlessness may occur early.

Parkinson Syndrome — Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome — Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System — Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological — There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with LIDONE may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects — Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with LIDONE therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with LIDONE.

Cardiovascular — Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological — Lens opacities and pigmentary retinopathy have not been reported where patients have received LIDONE (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with LIDONE.

Skin — Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with LIDONE usage alone.

LIDONE (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when LIDONE is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia — Although rarely reported with LIDONE (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION — Initial and maintenance doses of LIDONE (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50 to 75 mg/day.
- — Increase to 100 mg/day in three or four days.
- — Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- — An increase to 225 mg/day may be required in patients with severe symptomatology.
- — Some chronic, treatment-resistant patients may require up to 400 mg/day; (however, the long-term safety of 400 mg/day has not been established).

Elderly or debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild — 5 mg to 15 mg three or four times a day.
2. Moderate — 10 mg to 25 mg three or four times a day.
3. Severe — 225 mg/day may be required.

Dosage may be administered once a day.

DRUG INTERACTIONS — Potentiation of drugs administered concurrently with LIDONE (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when LIDONE is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE — Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of LIDONE (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of LIDONE (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by LIDONE in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized LIDONE from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of LIDONE is excreted unmetabolized in the urine.) However, poor response of the patient may justify use of these procedures.

While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized LIDONE in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED — LIDONE (molindone hydrochloride) capsules are supplied in bottles of 100 in the following dosage strengths and colors:

5 mg (**NDC** 0074-5542-13) blue and cream
10 mg (**NDC** 0074-5543-13) red and cream
25 mg (**NDC** 0074-5544-13) brown and cream

A Fond Letter to the Editor

DEAR FRANK,

What can one give to the Editor who has everything?

That, sir, was the question that plagued your Association as it searched for a suitable way of honoring your thirteen magnificent years as the ninth Editor of our *Journal*. As we have watched you at work, we have discovered the virtues that have guided your editorial pen: the breadth of your knowledge and interests, which, combined with your open-minded tolerance of controversy, have made the *Journal* a truly balanced forum for ideas; your unerring critical sense of what is appropriate for publication; your encouragement of younger writers and your soft answer that turneth away the wrath of the rejected author; your genius for the *mot juste* and the apt quotation; your unfailing wit and humor that have poured oil on troubled editorial waters and nourished the loyalty of your staff. What was there left, we asked ourselves, to bestow on a man with possessions like these?

As the shadows lengthened on our disheartened deliberations, an enthusiastic voice suddenly rang out, "I have it—a *Festschrift*!"

The collective response was as dreary as a Boston winter: "After thirteen years of editing, the last thing in the world Frank needs is more papers."

"Hear me out," replied the protagonist. "These will be no ordinary papers. Not one of them will Frank have seen in manuscript. Not one of them will he be required to read with an editor's critical eye, to send out for review, to appraise for acceptance or rejection. All this will have been done for him in an issue of the *Journal* prepackaged for his personal perusal. Like any ordinary citizen-subscriber, he will be able to sink back in his favorite armchair to read and reflect, to agree or demur, and even, if he is so minded, to write a letter to the Editor. That, I submit, would be a gift unique in the annals of editordom."

The arguments were irrefutable, the problem solved. This, then, is your own special copy of the *Journal*, edited from title page to colophon while you were out of the office. We have tried to select a table of contents to tempt your intellectual palate. Each of these papers, written by one of your countless colleagues and admirers, reflects an area enriched by your life and writings as clinician, scientist, humanist, administrator, editor, and admiral. Ransom Arthur Bunney gether the history and the nature of military on the basis of his experiences in the Navy you have given such long and loyal service. Bunney reviews the remarkable advances in psychiatry that have coincided with your years tor, and to which you have made your own contributions. Robert Butler discusses the aging, which you have always illuminated your youthful humor. Your distinguished leadership one of our country's foremost private mental is signalized by Robert Gibson in a paper to a major issue facing American psychiatry the place of private psychiatric institutions of patients with chronic mental illness. David argument for the vital importance of a knowledge psychiatry's past is underscored by the profound and scientific wisdom with which your own understanding of history have endowed you. Herbert Weiner applies the medical model to try in a paradox of truly Shavian proportions should delight your never-failing appreciation new, the unexpected, the creative.

It will gladden your Editor's heart to know of these authors leapt with enthusiasm at the to join in honoring you, and not one of them not one of them grumbled when faced with an almost impossible deadline for the submission contribution. Your Editorial Staff, too, labored hard and devotedly at the innumerable details of preparing the manuscripts for publication labor of love from us all, this *Festschrift* bears boundless esteem, the heartfelt good wishes deep affection of your Association, of the these papers, of your Associate Editors, of your rial Staff, and, through all of them, of that of readers of the *Journal* you have made among medical publications.

Am J Psychiatry 135, July 1978 Supplement

Reflections on Military Psychiatry

BY RANSOM J. ARTHUR, M.D.

The need for psychiatrists in the military was recognized for the first time during World War I, which involved millions of men in unusually protracted warfare. The policy of treating psychiatric casualties close to the front and returning soldiers to their military units as quickly as possible proved of great significance in the U.S. war effort. During World War II, the Korean conflict, and the war in Viet Nam, military psychiatry made great contributions and learned many lessons, both at home and abroad. The lessons learned by military psychiatry have important applications for the rest of medicine, especially in the fields of stress, crisis therapy, and community psychiatry.

IT IS A PARADOX that psychiatry, which is among the most pacific of disciplines, and the military, which represents organized bellicosity, have their moments of intimacy. Psychiatry and the military appear to be, as King Charles I said of monarch and subject, "clean different things." At first glance it would seem that surgeons, with their blunt, no-nonsense, aggressive style, might be more compatible with the military environment than psychiatrists, who often possess a liberal political outlook and a very high need for autonomy. It is true that the military has had little trouble recruiting surgeons and that surgeons have always been well represented in the ranks of military medical officers who achieve the highest grades and positions. Although the professional activity of the surgeon, particularly the surgery of war trauma, is indeed an integral part of the military mission, it does not quite ever occupy the central zone.

The core of military organizations, whether they are prepared to fight with bows and arrows or with hydrogen bombs, involves such items as leadership, courage, morale, motivation, perseverance, dereliction, malingering, and the age-old problems of drink and breaches of discipline. Psychiatry in the military setting finds itself inexorably drawn into considerations of these eternal verities of military life. Some psychiatrists in the military can concentrate on the purely professional activities of treating psychotic patients without reference to their patients' roles within the military organization. The vast majority of psychiatrists, however, must become involved in the structure of command and discipline whether they wish to or not. What is true for the peacetime military is doubly true for the military at war.

It is difficult to speak of psychiatry in the military before the latter portion of the nineteenth century, although psychiatric problems have always existed. Surely the erratic behavior of Caligula when he placed himself at the head of his Roman legions in the field cried out for psychiatric intervention, but there was to be no formalized military psychiatric assistance for almost another two millennia. Physicians during the American Civil War actively worked with soldiers who had what we would now recognize as various combat syndromes (1). The celebrated neurologist S. Weir Mitchell was an active medical officer during that conflict; he took an interest in the psychological problems of the soldiers in the Union Army. In the twentieth century, it was noted that during the siege of Port Arthur in the Russo-Japanese War of 1905 there were many casualties who seemed to have some kind of neuropsychiatric syndrome. They were diagnosed as syphilitic, but in view of what we learned about siege operations during World War I it seems unlikely that neurosyphilis was the real cause of their symptoms.

WORLD WAR I

It was World War I, the so-called Great War, that gave military psychiatry its initial formal surge. By 1914 psychiatry was a demarcated urban medical specialty; it was no longer primarily the province of mental hospital superintendents as it had been in the previous century. The great medical schools of Europe had professors of psychiatry who were directors of famous psychiatric clinics in such cities as Berlin and Vienna. Kraepelin had made his taxonomic contributions to psychiatry, and Bleuler had further delineated the concept of schizophrenia. The theories of Freud were known internationally, albeit often in a distorted and vulgarized way. The basic ideas of the unconscious and of psychodynamics were in the air. Neurosyphilis was a reasonably well understood entity. It must not be thought that psychiatry was, then or now, a truly high status specialty. However, there was a sufficient body of organized knowledge and a requisite number of working psychiatrists to enable them to deal with the unprecedented psychological problems arising from World War I in a far more systematic way

Dr. Arthur is Professor of Psychiatry and Associate Dean for Curricular and Student Affairs, University of California, Los Angeles, School of Medicine, Los Angeles, Calif. 90024.

0002-953X/78/007A-0002$0.55 © 1978 American Psychiatric Association

than would have been the case had a similarly catastrophic war occurred 50 years earlier.

The Great War involved millions of men in warfare of a protracted character not seen since the sieges of the Middle Ages. The horrors of trench warfare were greater in duration and magnitude than soldiers had previously endured. Major battles of the past, like Gettysburg or Waterloo, lasted two or three days, and even operations such as the siege of Richmond at the end of the American Civil War lasted but a few months. World War I dragged on year after erosive year and exposed men to constant danger, disease, fatigue, and untold horrors. It soon became apparent that there were large numbers of casualties among men who had suffered no obvious physical trauma. Twenty percent of the soldiers discharged for disability from the British Army had such psychiatric disorders as "shell shock," "war neurosis," or "neurasthenia" (2). There were soldiers who had gone blind, who had become unable to speak or hear, who had paralyzed limbs, or who shook so hard from anxiety that they were unable to function.

It was obvious that viewing these thousands of casualties as malingering on a mass scale was not the way to deal with the situation. There were attempts to treat such patients by methods common to the practice of neurology and psychiatry at that time: rest, diet, persuasion, sedatives, and moderate exercise. As one reads the case reports from both the Western Allies and the Central Powers, one is struck by the colorful phenomenological descriptions and the inadequacy of the theoretical framework of understanding (3). Physicians attempted to relate the type, extent, and severity of traumatic experiences and the individual character of the patient to the final outcome, but they had no unifying theory of traumatic neurosis. The syndromes of combat affected not only those who might have been expected to become shirkers but also soldiers and officers of demonstrated courage. Siegfried Sassoon (4), a man of supreme bravery, described his own experiences in a psychiatric facility for convalescent officers in England after three harrowing years in the trenches.

In spite of their desperate need for soldiers, the contending nations were relatively lax in their initial provision and monitoring of manpower. For example, Britain did not introduce conscription during the first year of the war. As the powers gradually became aware of the vast losses attendant on neuropsychiatric casualties, they developed a treatment doctrine pertaining to combat reactions that seemed to be suitable for both man and institution. In the U.S. Army, Cols. Thomas W. Salmon and Pearce Bailey were instrumental in stationing psychiatrists at the divisional level (5).

It was the duty of the psychiatric medical officer to integrate himself fully into the life of his division and to provide psychiatric services close to the front line. Psychiatrists provided rapid treatment of transient combat reactions that could be dealt with by rest, reassurance, provision of hot food, and the briefest kind of recuperation. These psychiatric medical offic[illegible] realized the enduring truth of combat psy[illegible] namely, that if one evacuated patients w[illegible] would otherwise be transient combat reacti[illegible] safe spot several hundred miles behind the lin[illegible] to the zone of the interior, it was virtually in[illegible] to get these soldiers to return to full com[illegible] Treatment close to the front line mobilized [illegible] dier's primary psychological weapon: iden[illegible] with his comrades in his military unit. A soldi[illegible] had a strong sense of guilt about deserting [illegible] while it was under heavy fire, no matter h[illegible] pelling the reason.

The American psychiatric program proved [illegible] markably successful. After initially high leve[illegible] chiatric casualties, the rate for the U.S. Arm[illegible] a rather low order of magnitude. To be sure, [illegible] ordinarily high quality of the vigorous America[illegible] their freshness in comparison with the exhau[illegible] ropeans, and the constant series of victories d[illegible] summer and early autumn of 1918 no doubt co[illegible] to their superb morale and low rate of psyc[illegible] disability. Nevertheless, the efforts of a very [illegible] chiatrists proved of real significance in the fu[illegible] of the American war effort in the European t[illegible] operations.

The war had a profound impact that [illegible] beyond those psychiatrists who were on [illegible] vice. The unremitting horrors of the war [illegible] Sigmund Freud to make considerable modifi[illegible] his thinking about instinct theory and drea[illegible] tion. On the basis of the reported experience[illegible] war, he realized that certain dramatic events [illegible] duce stereotypic dream patterns of a persist[illegible] that had little to do with wish fulfillment. [illegible] after witnessing the appalling carnage of the [illegible] hard to deny the strength of aggressive and ca[illegible] motivational forces in human life. Freud, wh[illegible] in 1856, had spent his entire life in an era [illegible] general European war, let alone a world w[illegible] easy in the peaceful Victorian twilight to reg[illegible] gressive and death-connected aspects of [illegible] tivity as of lesser importance than the libidi[illegible] views could not be held seriously in 1919. F[illegible] *Beyond the Pleasure Principle* (6) after the [illegible]

By 1918 military psychiatry had discove[illegible] ber of elemental principles. The first was [illegible] longed exposure to a situation of constant c[illegible] deprivation could result in various disa[illegible] dromes not brought about by obvious physic[illegible] Second, this type of reaction to prolonge[illegible] stress was very widespread. Third, the factor[illegible] to do with the social support given to a sold[illegible] unit and leaders had important prophylactic [illegible] the prevention of combat reactions. After [illegible] many of these crucial lessons were forgotte[illegible] in the United States, in spite of the extens[illegible] mentation given in volume 10 of the *Medical Depa[illegible] ment of the United States Army in the W[illegible] War*. This volume was apparently read as an impe[illegible]

by the Royal Army Medical Corps in Britain, but its lessons seemed to have vanished from the American consciousness.

In between the wars, during what Robert Graves called "the long weekend," the regular armed forces were kept at a ridiculously low level; the medical departments were correspondingly small (7). There was only a handful of psychiatric specialists in the Army and Navy. There were 35 psychiatrists in the Army, and only 4 of these were diplomates of the American Board of Psychiatry and Neurology. There was no carefully thought-through contingency plan for the treatment and rehabilitation of psychiatric casualties. To anyone unfamiliar with the melancholy and isolated history of psychiatry in general, this glaring omission would seem very odd. Those with a knowledge of the past would know that a very large number of psychiatric casualties could be expected in a general war. Nevertheless, little thought was given to planning in this area. Psychiatric specialists were not highly regarded in either civil or military life, and the kind of cooperation and visionary thinking necessary to adequately prepare a psychiatric program was largely lacking.

WORLD WAR II

Fortunately, many of the leaders of Army and Navy psychiatry during World War II were drawn from a group of experienced civilian psychiatrists. I could mention several hundred contributors by name, but any list of distinguished wartime psychiatrists would do injustice to others whose contributions might have been equally great but not as well recognized. Francis Braceland was one of the true pioneering leaders of modern Navy psychiatry. Already Dean of Loyola Medical School, after commissioning in the Naval Reserve he recruited outstanding psychiatrists for naval service. He became assistant head of the Neuropsychiatric Section (later Branch), formed under the leadership of Captain Kennedy in 1942, and in 1944 was appointed head of the Branch. During the course of the war, under his outstanding leadership, the U.S. Navy expanded from 8 psychiatrists to approximately 980. Throughout that period the Neuropsychiatric Branch enjoyed the confidence and cooperation of the Navy Surgeon General, Admiral McIntire.

Dr. Braceland wrote extensively on problems of Navy psychiatry, including the areas of selection, combat reactions, and institutional variables in the incidence of psychiatric disease in the military (8, 9). Among the important duties that he and others were called on to perform during the course of the war was the crisis therapy of highly placed officers and civilian officials who developed severe psychiatric reactions. Psychiatrists who were given these missions had to work under all the adverse conditions that are connected with the treatment of VIPs, but their therapeutic task was given a special urgency when, for example, the individual was a key member of the team working on the atomic bomb.

Among the major tasks of military psychiatry during both world wars was the psychiatric and psychological screening of individuals with mental handicap or psychiatric disorder of sufficient magnitude to preclude the possibility of successful military service. The screening out of men and women who were grossly impaired was of crucial importance to the effectiveness of the fighting forces (10). A more controversial area, however, was the detection of individuals with personality deficits labeled as immaturity or unstable character. Many psychiatrists prided themselves on being able to distinguish recruits who would not become good soldiers or sailors on the basis of a three-minute interview. There were no studies in wartime that conclusively demonstrated the validity of such predictions. Research on this topic was performed, but it failed to include a control group of individuals who were enlisted in spite of adverse psychiatric opinion with which to compare the psychiatrically cleared group. Postwar research at the Navy Neuropsychiatric Research Unit has cast great doubt on the ability of the psychiatrists to screen out at a level greater than chance those individuals who would later become ineffective sailors and Marines. The studies were carried out with cohorts from 1960 and 1961 (11). However, the study conditions were different from those existing during the war, and it is possible that wartime screening was effective.

When World War II began, the U.S. Army did not immediately build on the carefully worked out psychiatric plans of 1918. Instead, a somewhat ramshackle approach to the problems of psychiatric casualties was initially taken by the Army high command. The number of psychiatric casualties was initially shockingly high. During wartime the incidence of psychosis usually rises rather little (12). In fact, for well over 60 years the incidence rates of psychosis in the U.S. Navy varied scarcely at all under both peacetime and wartime conditions. However, situational reactions, psychoneuroses, and character and behavioral disorders showed great changes in incidence rates according to circumstances. The recorded incidence rates of these conditions depend not only on environmental variables but also on medical administrative policies. It is notorious that line commanders as well as medical commanders influence the diagnoses given to certain categories of military patients.

By 1943, however, both the Army and the Navy had developed a strong cadre of superb psychiatrists, many from civilian life, who were being used, by and large, in a correct manner. There was a strong emphasis on sound combat psychiatry and rapid return to duty. In addition to the psychiatrists stationed at some proximity to front-line fighting, there were others on duty in psychiatric wards, base hospitals, psychiatric hospitals, psychiatric units on hospital ships, in administrative posts at higher headquarters, and in combat air crews in the Army Air Corps, later the U.S. Air Force. In fact, some of the most dramatic, gripping, and terrifying stories of the effects of combat stress

came from psychiatrists who were stationed with the air arm (13). Psychiatry proved itself an important tool in maintaining air crew effectiveness. Flight surgeons, of necessity, had to have at least a rudimentary knowledge of practical psychiatry in order to function effectively. By the end of the war both services had superb psychiatric capability. A roster of leaders of military psychiatry and psychology during the war reads like a "Who's Who" of pre- and postwar American academic psychiatry and clinical psychology. After the war those who had served in posts of responsibility during the war itself were well equipped to move into important academic posts in an era of expansion.

THE LESSONS OF WARTIME PSYCHIATRY

The psychiatric experience of both world wars provided a number of lessons that proved to be of general interest. Military psychiatrists were first to describe the specific features of combat syndromes. They documented the overt anxiety, recurrent nightmares, startle reactions, exhaustion, and other cardinal features of combat stress. Combat reactions are not monolithic. Their subcategories were distinguished by war psychiatrists in the field. For example, patients might be classified as showing simple combat fatigue, hysteric or anxiety reaction type, or psychotic reaction type. In each instance the syndrome was a result of the kind, amount, and duration of stress superimposed on the preexisting mental status and character of the patient, his characteristic coping abilities and mechanisms, and the morale of and support given his unit. Unit morale, in turn, depended very often on excellence of leadership.

Military physicians were also pioneers in the description of the concentration camp syndrome (KZ syndrome), which represents the classic instance of a clearly identifiable syndrome arising from extreme stress. This syndrome developed in a fearsome situation in which there was a pervasive threat of death. The syndrome is characterized by difficulties in mentation, anxiety, depression, insomnia, and gastrointestinal and other persistent physical symptoms (they have persisted for 35 years now) (14). The whole basic idea of crisis and crisis therapy clearly owes much to descriptions of the traumatic disorders of war and their treatment. The increase in interest in therapeutic processes, and most particularly the surge in the popularity of group therapy, as well as the basic thrust of a therapeutic community in psychiatric practice, arose in part out of the wartime experience, particularly that of the English military psychiatrists.

One of the most important phenomena of the war was the exposure of large numbers of nonpsychiatric physicians and future physicians to the experience of military psychiatry. Specialists and general practitioners who had thought of psychiatry in terms of remote alienists or isolated mental hospital work were exposed to a vast variety of psychological disturbances arising in men and women whom they had kn... sane and ordinary. RESEARCH

It was during the 1950s and 1960s that the ... Navy fully developed permanent psychiatr... facilities: the Walter Reed Army Institute o...

in Washington, D.C., and the Navy Medical Neuropsychiatric Research Unit (now the Naval Health Research Center) in San Diego, Calif. The major theme of both enterprises is research on the effects of stress. Biological, social, and psychological approaches are used. For example, the work of Mason (16) and his fellow investigators at Walter Reed on the neuroendocrinological aspects of stress represents an important contribution to biological science in general.

The Naval Health Research Center in San Diego has concentrated on research on the epidemiology of psychiatric disorders in the Navy and Marine Corps, the environmental factors influencing health in military personnel, the effect of stress on disease onset and health patterns, the effect of stress on performance in such groups as Navy aviators and under-water demolition team members, as well as research on the most effective patterns of sleep and rest in the maintenance of vigilance and efficient task performance. Other important studies carried out at the Navy unit include studies on the prediction of successful military performance (17). More recently, the Center for the Study of Prisoners of War was developed in San Diego to study all aspects of the captivity experience and develop rehabilitation plans. This center also studied the families of the released prisoners. The mission later expanded to include studies of the stresses and strains of military families in general. Although it is surely correct that many of the studies have an applied focus, most have important implications for a particular area of biobehavioral and psychiatric sciences. The sum of the discoveries represents a body of work in which the medical departments of the Armed Forces can take justifiable pride.

THE VIET NAM CONFLICT

There can be no doubt that the war in Viet Nam, with its malignant effects on life in Southeast Asia and in the United States, had injurious effects on the American military—and on military psychiatry as well (18). It was difficult to maintain the morale of members of the Armed Forces during this troubled period. The psychiatric precepts that had proven so useful in wars with a clearly identified enemy seemed less obviously applicable during a war monumentally unpopular among military and civilian populations alike. Lengthy exposure to prolonged combat and threat of death without any definite hope of escape were not present in Viet Nam. The amount of time that an individual would spend in Viet Nam, provided he survived, was fixed. Combat was often of a highly sporadic character against a foe who, except for an occasional pitched battle, preferred to come and go out of the shadows.

Although the danger of death and mutilation for our men was very real, as the tens of thousands of combat deaths attest, the combat in Viet Nam was much different from that experienced in the trenches of Flanders in 1916, during the siege of Stalingrad in 1942, or during the prolonged battles along the 38th parallel in the Korean conflict. Military psychiatrists had to cope with a new type of patient with new types of stress. No longer was there necessarily a basically motivated soldier fighting as part of a proud and recognized military unit, who felt guilt about leaving his comrades, who might be suffering temporarily from nightmares, anxiety, and exhaustion, but who had a basic desire to return to do his duty. Instead, there were often military patients whose motivation to return to duty was at best ambiguous. The amounts of combat stress received were imprecisely known. There were often various adventitious elements complicating the clinical picture, such as the unprecedentedly large number of men taking drugs. It is not possible to compare directly the psychiatric casualty rates of the Viet Nam conflict with those of previous conflicts. The Viet Nam figures were widely publicized as being lower than those of the past, but it is not clear what significance to attach to data of differing types. The short tours of duty (one year) and peculiar nature of the combat had no exact parallel in previous wars. The special psychiatric problems of Viet Nam veterans were not confined to the wartime period and have continued to loom large in the operation of certain Veterans Administration programs for such individuals (19).

ETHICS

Another problem that arose in an acute form during the time of the Viet Nam conflict was the question of the ethics of military medicine. With the growth of ethical hypersensitivity during the past few years, questions have arisen as to whether it is possible to reconcile one's oath as a physician (implying as this does the total dedication of oneself to the welfare of the individual patient) with the institutional demands of the military, in which the individual is subordinated to an overall group purpose. This ethical conflict is perhaps most marked in military medicine associated with combat. For example, is the surgeon justified in attempting to repair an injury as quickly as possible so that the individual can swiftly return to combat, where he might well be injured again or killed? Is the military psychiatrist justified in rapidly treating combat fatigue? Is the physician ethical in using his patient's guilt about deserting his comrades and his identification with his unit in order to have him quickly returned to combat, where he might soon be killed? Should not the psychiatrist counsel this patient to evade his duty and return to the safety of the zone of the interior? Should not the psychiatrist help the soldier to rationalize that he was in fact fighting in a wicked war? Should not the psychiatrist affirm that all wars are wicked, that the patient's own self-interest lay in expunging any sense of guilt or obligation to others and in seeing, in a clear-eyed way, what is best for him alone? During the Viet Nam conflict such choices posed a Hamlet-like dilemma in which ethical fastidiousness became a

serious concern within the context of an affluent society in the midst of a distant and unpopular war in which national survival was not in jeopardy.

Moral dilemmas of military medical practice were mentioned in works dealing with military psychiatry in both of the world wars but were quickly dismissed. It was felt that there was no violation of the physician's ethical role in his military medical work and that psychiatrists were obliged, as a matter of duty, to restore a man to functional integrity by repairing the ravages of a combat neurosis. It was assumed that, restored to mental health, the soldier would necessarily wish to do his duty.

It must be said that scrupulosity on this issue could only be the product of recent times. In the first place, in centuries before the nineteenth, the social position of physicians, save for a very few, was sufficiently low to make them glad to have a military post without giving serious thought to moral considerations. During the Roman times physicians were slaves, and even in the last century the commission as an officer that the military surgeon might receive was considered a higher honor than his medical qualifications per se. It has only been in the twentieth century that the social and economic status of physicians has risen to a point where it exceeds that of military officers. The major wars of this century have been seen by both sides as ideological struggles in which national survival itself was at stake. The Kaiser and later Hitler and the Japanese militarists were considered so wicked by their enemies that the world wars were thought of as holy missions. Eisenhower spoke of a "crusade in Europe," and the subsequent disclosure of the barbaric activities of the Nazis made this feeling not implausible. It was only with the arrival of a war of stupendous unpopularity involving a nation possessed of unprecedented comfort and affluence that moral sensitivity arose about a myriad of war-related issues. Questions about medical ethics are the subject of innumerable discussions that do not often lead to definitive answers. Most people, through one mental process or another, manage to reconcile their duties as citizens, physicians, and organizational members without serious moral repugnance. In any case, with the ending of America's direct participation in war, the moral issues of combat psychiatry are now moot.

Many institutions in American life suffered an erosion of authority and loss of public goodwill as the result of the Viet Nam conflict. The military, in general, was prominent among the institutions injured. In turn, military psychiatry is in a subdued phase as compared with 15 years ago. The number of psychiatrists in uniform has dwindled considerably, and there are few senior people left. Nevertheless, the situation is not so bad as it was before World War II. Psychiatry is still recognized as an important entity within the military forces. The perennial tensions between psychiatry and the military command continue. Commanding officers still wish to use psychiatric services as a way of disposing of troublemakers. As ever, there are still bizarre fantasies on the part of high-ranking lin[illegible] that psychiatrists are able to read people's [illegible] have the ability to screen out potential failu[illegible] programs in which the failure rate is less than [illegible] thousand. On the other hand, the military is [illegible] more accepting of the possible worth of al[illegible] programs and other psychiatric rehabilitative [illegible] ors for military families and active duty pers[illegible] cluding high-ranking officers. A psychiatrist [illegible] cellent professional and political skills is still [illegible] tion to become a central figure in an isolate[illegible] base in the areas of discipline and morale, pr[illegible] or she makes the necessary effort and has a sy[illegible] ic commander.

Military psychiatry has made important [illegible] tions to psychiatric thinking in general duri[illegible] six decades. Just as Lind, Beaumont, an[illegible] Reed, all distinguished military physicians, [illegible] nal advancements in medicine, psychiatric [illegible] particularly the field of stress, is much indebt[illegible] coveries of military psychiatry in discipline[illegible] from neuroendocrinology to psychoanalysis.

Drug Therapy and Psychobiological Research Advances in the Psychoses in the Past Decade

BY WILLIAM E. BUNNEY, JR., M.D.

There have been major advances in the treatment of psychoses in the past decade, particularly in the area of maintenance therapy with lithium, tricyclics, and neuroleptics. Such efforts have been enhanced by methods of relating plasma drug levels to clinical efficacy. Research in genetic factors, the mode of action of pharmacological agents, and hormonal influences on psychopathology has added to our theoretical understanding of the psychoses, and we can hope for further advances from sophisticated new methodological tools. Promising areas of investigation include the search for genetic markers, studies of postsynaptic neuronal receptors, and examination of the effects of polypeptides, including endogenous opioid compounds.

IN THE PAST DECADE significant advances have been made in the pharmacological treatment of the psychoses. Furthermore, new methods and hypotheses in the area of psychobiology provide the promise of rapid expansion of knowledge in the future.

Perhaps the most important therapeutic advance that has occurred in the drug treatment of schizophrenia and affective illness during this period is the accumulation of evidence concerning the value of long-term drug maintenance with lithium and tricyclic compounds in affective illness and with neuroleptics in schizophrenia. A large number of studies have shown that lithium carbonate markedly decreases the intensity of recurrent episodes of depression and mania in at least 60% of patients maintained on the drug (1, 2). Some studies suggest that maintenance therapy with tricyclic compounds is also effective in decreasing the incidence of recurrent depressive episodes in unipolar patients (3). Studies in the past 10 years investigated the untreated relapse rate one year after resolution of an acute depressive episode (3, 4). The mean relapse rate in these studies was 64%, with a range of 36%–92%. Additional studies (4) addressed the issue of how the relapse rate would be affected by continuation of tricyclic antidepressant medication and found a mean decrease in relapse rate of 50% with maintenance treatment. Investigations are currently in progress that will provide further data concerning the value of long-term tricyclic maintenance, the doses required, and whether a combination of tricyclic and lithium is more or less efficacious than either treatment alone.

In schizophrenia, it is equally convincing that the long-term maintenance therapy with neuroleptics can decrease the need for rehospitalization and that rehospitalization rates can be further decreased when drug therapy is combined with psychotherapies. The efficacy of neuroleptics has been demonstrated in 26 uncontrolled nonblind studies and 22 controlled double-blind studies (5). Patients taken off phenothiazines after initial improvement show a high rate of relapse through the third and sixth months. The relapse rate continues to increase until 12 months after discontinuation of phenothiazines, when there is a plateau in the cumulative frequency curve of relapse rates. It has also been reported, although recently questioned, that use of the long-acting depot phenothiazines, fluphenazine enanthate and fluphenazine decanoate, further decreases recurrent hospitalizations, probably as a result of avoiding compliance problems of daily neuroleptic maintenance (5). Long-term maintenance with neuroleptics is associated in some patients with the development of tardive dyskinesia (6). Concern at the present time is due to an increased prevalence of tardive dyskinesia and the fact that some of the dyskinesias are irreversible and treatment is often unsatisfactory. If dyskinesias are recognized early, discontinuation of neuroleptics is often effective. However, the physician may then find himself in a therapeutic dilemma, since the patient's condition may require continued treatment. Thus a major task of current research is understanding the mechanism of movement disorders.

DRUG PLASMA LEVELS

Relating plasma levels of drugs to their effectiveness has provided another possible advance in psychotherapeutics, both in avoiding toxicity and in establishing therapeutic levels. This has allowed the safe administration of lithium in the correct therapeutic dose to hundreds of thousands of individuals.

Methods have now been developed to evaluate vari-

Dr. Bunney is Chief, Biological Psychiatry Branch, National Institute of Mental Health, Bldg. 10, Rm. 3N212, 9000 Rockville Pike, Bethesda, Md. 20014.

ous tricyclic compounds and some of their active metabolites in plasma. These determinations are beginning to gain wider clinical use. Different individuals given exactly the same dose of a tricyclic compound can show a 10-fold to 20-fold variation in plasma levels. Thus on the same dose some individuals may be receiving too much of the drug, while others have a plasma drug level below the therapeutic range (4). This results from a variety of considerations, including a number of genetically controlled factors affecting the pharmacokinetics of the drug. Absorption and metabolism are critical variables. It has been reported that the unbound portion of the tricyclic may vary among individuals, unrelated to dose, from 5.4% to 23% (7, 8). Since only the unbound portion of plasma tricyclic is pharmacologically active, two individuals on the same dose may differ markedly in the amount of the drug that is available to the target tissue. An inverted U-shaped curve relationship between nortriptyline plasma concentration and therapeutic response has been reported (9). This has been described as a "therapeutic window," which was reported to be 50–150 ng/mg for nortriptyline. Below or above these values, patients did not have a clinical response. An inverted U-shaped curve relationship has also been suggested for amitriptyline (10). However, a larger collaborative World Health Organization study showed no relationship between plasma level and clinical response (11). A linear relationship has been reported for imipramine in which there apparently is no falloff of therapeutic effects at higher plasma levels (12). Thus it appears that nortriptyline and amitriptyline are compatible with the concept of a therapeutic window, while imipramine does not appear to have an upper limit for therapeutic effect.

Attempts have been made to evaluate neuroleptic levels in patients and to relate them to therapeutic change. The metabolism of many of the neuroleptics, including chlorpromazine, is so complex, including many active and inactive metabolites, that drugs with a simple metabolism such as butaperazine may be more fruitful for pharmacoclinical response correlations (13–15). Butaperazine was reported to have an inverted U-shaped dose-response curve (16). More recently, a method for stereospecific ^{3}H-spiroperidol binding in plasma has been described that measures dopamine receptor binding (17). This method may be important for determining and comparing therapeutic levels of different neuroleptics as well as measuring total dopamine binding when a combination of drugs is administered.

In the future it is to be expected that more effective therapeutic levels can be achieved through the use of plasma values of tricyclic compounds, neuroleptics, and receptor binding assays. The availability of plasma determinations for amphetamine and methylphenidate in the treatment of minimal brain disorder holds similar promise for eventually arriving at more accurate designations of therapeutic drug levels for a given patient (18, 19).

MAJOR INFLUENCES IN THEORETICAL UNDERSTANDING OF THE PSYCHOBIOLOGY OF THE PSYCHOSES

Increasing emphasis has been placed on ur[illegible] ing the genetic influences on schizophrenia [illegible] fective illness. It has been well documented [illegible] concordance rate for manic-depressive illness [illegible] identical twins is approximately 13%, while [illegible] cordance rate in identical twins is over 60% [illegible] ies of biological and adoptive relatives of schizophrenic [illegible] ics have also indicated the existence of a genetic factor in schizophrenia (21–23).

Over the past decade drugs have been identified that activate the symptoms of various psychiatric disorders. For example, 20 mg of *d*-amphetamine can produce psychotic symptoms in a subgroup of schizophrenic patients (24), but the same dose rarely produces psychotogenic effects in normal individuals or depressed patients. Monoamine oxidase inhibitors and tricyclics can precipitate manic symptoms in bipolar patients (25). Conversely, as noted previously, many psychological agents can decrease psychopathology and block the recurrence of future episodes. It is of interest that all of the drugs which activate or alter psychopathology in man have effects on neurotransmitter systems in brain. For example, amphetamine releases and blocks reuptake of dopamine and norepinephrine presynaptically, whereas the neuroleptics that are effective in treating schizophrenic patients block postsynaptic dopamine receptors.

Data derived from animal studies concerning the mode of action of various pharmacological agents that can increase or decrease psychopathology have guided biological theories about the roles of catecholamines and indoleamines in affective illness. It has been suggested that a functional deficit of catecholamines and indoleamines exists during depression and activity may increase during mania (26–28). Furthermore, it has been hypothesized (29) that an increase in functional activity of dopamine may be associated with some of the symptoms of schizophrenia. There are also pharmacological and anatomical data suggesting an interaction between γ-aminobutyric acid (GABA) neurons and dopamine neurons, and it has been proposed that GABA may also be involved in the pathophysiology of schizophrenia (30).

Drugs are now available for clinical investigation that facilitate the study of the relationship of brain mechanisms to behavioral responses. Drugs with relative selectivity may block enzymes in catecholamine neurotransmitter synthetic pathways, effect storage and reuptake, act as postsynaptic receptor agonists or blockers, or block degradative enzymes. For example, as α-methyl-*p*-tyrosine, which inhibits the rate-limiting step in the formation of the neurotransmitters dopamine and norepinephrine, or piribedil, a relatively specific dopamine agonist, provide powerful pharmacological tools for the further investigation of neurotransmitter hypotheses of psychoses. Further [illegible]

compounds are becoming available that may preferentially affect hypothesized presynaptic rather than postsynaptic receptors (i.e., low-dose apomorphine). Other compounds may affect various steps in the postsynaptic amplification of the received signal from the postsynaptic receptor.

Another area that has had a major influence and has gathered increasing momentum during the past few years involves studies of the role of hormones in psychopathology. It has been well known for many years that hyper- or hypofunction of most of the endocrine systems can be associated with psychopathology. It has also been established that in depressive illness there is an altered pattern and increased excretion of cortisol with more frequent peaks and higher nocturnal levels (31). Some of the important pioneering work in the relationship of ACTH and cortisol to psychopathology and mood was conducted by Braceland (32–36). Endocrine releasing factors and other small CNS peptides previously thought to play a role only in the regulation of peripheral acting hormones have been shown to have receptor sites in the CNS and to have behavioral effects.

It has more recently become possible to measure prolactin released from the pituitary both in plasma and cerebrospinal fluid. This release is partially under the inhibitory control of dopamine; therefore, indirect dopamine agonists such as L-dopa tend to decrease prolactin levels, whereas most neuroleptics that block dopamine receptors produce an increase in prolactin.

Another influence in developing theoretical concepts of psychoses involves the realization that parkinsonian illness can be successfully treated with L-dopa. Since chronic schizophrenia may be due to some profound disruption in brain metabolism or physiology, the search continues to identify anatomical areas of dysfunction in the brain and to find compounds that might reverse this dysfunction.

NEW RESEARCH METHODS

New methodological tools have been responsible for some of the progress that has been made and will certainly contribute to future discoveries in the field of the psychoses. The development of the metabolic psychiatric research ward, concomitantly utilizing longitudinal nurses' rating scales, continuous 24-hour urine samples, plasma samples, and periodic cerebrospinal fluid samples, has had an important influence on the field. Physical activity has always been a confounding factor in most of the biochemical studies in man, and it is now possible to monitor activity on a continuous 24-hour basis in an extremely accurate manner (37). It is also possible to monitor sleep and dreaming parameters in a longitudinal fashion in a number of patients simultaneously. The development of gas chromatography and, more recently, mass spectrometry, radioenzymatic techniques, and radioimmunoassays has greatly increased the accuracy with which scientists can estimate levels of neuroendocrines, amines, and their metabolites in urine, plasma, and cerebrospinal fluid.

The probenecid technique of blocking the exit of acid metabolites from the cerebrospinal fluid has allowed investigators to estimate turnover of various neurotransmitters in brain and spinal cord, and more recent isotope techniques using differential labeling of origins of urinary catecholamine metabolites and carbon-labeled dopamine may provide even more accurate methods (38). The development of models of psychoses in rats and in primates has also provided a way of testing various new drugs and theories as they relate to clinical problems.

One of the most recent technical advances for the potential study of brain function in psychopathology involves the use of emission computerized axial tomography (ECAT scan) in combination with infused 2[^{18}F]fluoro-2-deoxy-D-glucose. This procedure would provide three-dimensional information concerning regional alterations in brain energy metabolism, which would theoretically reflect regional differences in functional neuronal activity (39, 40, and unpublished data from M. Reivich, D. Kuhl, and A. Wolf).

NEW AREAS WITH POTENTIALLY IMPORTANT IMPLICATIONS FOR FUTURE INVESTIGATIONS

A good deal of the work has been completed in searching for genetic markers in psychiatry, particularly in bipolar affective illness, using red-green color blindness and the Xg blood antigen. However, there now seems to be some reason to question the validity of both of these as markers of affective illness (41). Other genetic markers currently under investigation include enzymes involved in the synthesis and degradation of neurotransmitters such as catechol-*O*-methyltransferase (COMT), monoamine oxidase (MAO), dopamine-β-hydroxylase (DBH), HLA antigens, blood groups as markers, and polymorphic markers such as red cell enzymes and serum proteins. Possible genetic factors in pharmacological responses are also being studied. What is needed is a genetic marker that can be applied to each individual in a pedigree and then used to successfully predict which individuals are at risk. The marker must first be shown to be heritable. A homogeneous subgroup of patients with the disorder must be identified on a clinical, biological, or pharmacological basis, and the transmission of the disorder among families must be found to be related to the transmission of the marker. To date, no such marker has been definitively identified. However, this strategy obviously holds great promise for the employment of preventive measures, and an intensive search for such markers is currently under way (42).

Previous work has focused on the presynaptic neuron in attempting to understand the role of synthesis, release, and reuptake in various animal systems and their possible implications for psychopathology. More

recently, various techniques, including receptor binding assays, have been developed to study postsynaptic neuronal receptors in animals and man. Furthermore, drugs with specific actions on specific neurotransmitter receptors have been used, such as dopamine and norepinephrine agonists and receptor blockers. It has also been suggested that it would be particularly useful if one could synthesize neuroleptics that blocked dopamine receptors in one area of the brain and not in another. The development of neuroleptics that did not affect the nigrostriatal area might result in a lower incidence of extrapyramidal side effects or tardive dyskinesia and would be of clinical and theoretical importance. Currently, pharmaceutical companies are actively searching for such compounds. Also, it has been clearly demonstrated in animals that pharmacological agents can produce supersensitive receptors, as manifested by either an increase in receptor sites or an increase in affinity for a compound. The application of the concept of super- and subsensitive neurotransmitter receptors to human disease, to psychopathology, and to the action of drugs may have important implications. For example, it has been hypothesized that tardive dyskinesia may relate in part to the development of supersensitivity following many years of neuroleptic treatment. A further understanding of this phenomenon could lead to new treatments for tardive dyskinesia or successful preventive methods.

Another new and highly preliminary area is the use of renal dialysis to remove hypothesized endogenous psychotogens in an attempt to treat schizophrenia (43). Scientists agree that what is needed at this point are double-blind evaluations of this technique. If it proves to be useful in some schizophrenic patients, then an intensive and probably long search will ensue for the critical ingredient of blood that is removed by dialysis.

Finally, specific opiate receptors identified by chemical binding techniques have been discovered in brain and other tissues (44). A number of peptides, methionine and leucine enkephalin, and β-endorphin as well as nonpeptide opiate-like substances that bind to opiate receptors have been discovered. These discoveries have initiated a search for a physiological role of these opioid substances. The pharmacological effects of opioid alkaloids provide the best clues for the effects of endogenous opioid compounds (endorphins). Since morphine and its congeners affect mood, pain appreciation, sleep, respiration, and release of pituitary hormones, these physiological functions are currently under investigation.

A number of strategies are being used to study possible functions of endorphins in man. These involve the direct administration of endorphins, attempts to measure endogenous opioid substances in urine, plasma, and CSF by radioimmune and radioreceptor assays, attempts to increase the release of endorphins through a variety of techniques, including experimental induction of pain and stress, implantation of electrodes in the brain, and, finally, the use of narcotic antagonists to study the effects of blocking the endorphin systems. The latter strategy is the one that [illegible] used most extensively (44). Two relatively [illegible] cotic antagonists in current use are naloxone and naltrexone, which reverse the effects of endorphins. Thus if endorphins act to regulate [illegible] neurophysiological function, a pure narcotic antagonist administered to man should alter such [illegible]

It has been suggested that endorphins [illegible] changed in schizophrenia, although current [illegible] is inconclusive. It has also been suggested that catatonia seen in animals following the administration of endorphins may relate to neuroleptic-induced catalepsy and to human catatonia. To date one study (45) and two double-blind studies (46, 47) suggested that naloxone may temporarily reduce auditory hallucinations and perhaps other symptoms of chronic schizophrenia. However, five other studies have failed to replicate this finding (48–52).

There are also a number of theoretical [illegible] suggesting that endorphins may play a role [illegible] Opioids produce euphoria that is similar [illegible] phoria associated with mania. It has been suggested that the behavior of cats given morphine may be a model for mania (53, 54). Furthermore, schizophrenic patients experience markedly less pain in response to experimental stimuli than do normal [illegible] which would be compatible with a theory [illegible] endorphins in mania (55). It has been reported that naloxone produced a decrease in some of the symptoms of mania in a small percentage of patients. However, another study found no antimanic effect of naloxone (56). No therapeutic effects of naloxone in depression have been reported to date.

It was also reported in one single-blind [illegible] one of the opioid compounds identified in the pituitary, β-endorphin, may have therapeutic [illegible] schizophrenia and other psychiatric disorders [illegible]. These findings require study in other laboratories under double-blind conditions. If any of these findings is confirmed, even in subgroups of psychiatric patients, an entirely new field will be opened in attempt to understand psychopathology.

In addition to the morphine receptor, several investigative groups have recently identified a benzodiazepine receptor (58, 59). Since benzodiazepines are the most frequently used psychoactive drugs, understanding of how they interact with the brain, what neurotransmitters may facilitate or inhibit their interaction, and, ultimately, whether there is an endogenous "anxiety-related" compound that binds to this receptor is of critical importance in our understanding of anxiety.

CONCLUSIONS

Major advances have been made in our [illegible] crease the recurrent suffering of individuals with chronic manic-depressive or schizophrenic illness through the long-term use of pharmacologic [illegible]

alone or in combination with a variety of psychotherapeutic techniques. The application of plasma levels for the establishment of accurate therapeutic windows may also increase the number of patients who respond to drugs. The mode of action on neurotransmitters in the brain of many of the drugs now used has led to some provocative and productive hypotheses concerning the role of the neurotransmitters dopamine, norepinephrine, serotonin, and GABA in these illnesses. Furthermore, it has been suggested that hormones may play a critical role in modulating the effects of these neurotransmitters. Methodologies such as the development of psychobiological research wards, new instrumentation for the analysis of body fluids, and new models of psychosis all promise the further expansion of our knowledge of these fields. New areas such as the role of polypeptides (including the endogenous opioid compounds) in modulating behavior and the intensive study of neurotransmitters and their receptors may lead to alternative hypotheses and treatments for the psychoses.

Thoughts on Aging

BY ROBERT N. BUTLER, M.D.

Aging has not received attention in proportion to its effect on the life of every individual. Much of society's reluctance to deal with old age results from "ageism," a personal and cultural dread that stems from a view of aging that sees only the negative aspects. If we are to understand human development, we must learn about its outcome, old age. One means of doing this is to listen to the reminiscences of old people. Psychiatrists can apply their special expertise in working to overcome ageism. Current and future legislative and research efforts can help identify and resolve some of the economic and physical problems of the elderly and thereby improve the quality of their lives.

> Every man desires to live long, but no man would be old.
>
> —Jonathan Swift

AGING IS an intrinsic part of the life cycle. Old age is experienced by an increasing number of people, yet it is still feared and denied by many. In part, this fear stems from ignorance, for aging has not received attention in proportion to its effect on the life of every individual. One manifestation of society's reluctance to come to terms with aging is its pervasive prejudice against the old. Moreover, the triumph of a longer life expectancy in this century is regarded as a problem, and the elderly are often more reviled than revered. Although childhood development has been studied intensively and examinations of death and dying are gaining popularity, until recently aging has been all but neglected by scientists. Can we really expect to understand early development fully without looking at the outcome of that process, old age? As interest in aging grows and the fields of gerontology and geriatrics expand, these issues deserve serious thought.

"AGEISM"

"Ageism" is a profound psychosocial disorder characterized by institutionalized and individual prejudice against the elderly, stereotyping, myth-making, distaste, and/or avoidance. It is to be distinguished from gerontophobia, which is a more rare expression of unreasonable fear, often accompanied by a hatred of older people. Ageism, like racism and sexism, is a way of pigeonholing people rather than viewing them as individuals with unique ways of living their lives.

The manifestations and symptoms of ageism pervade our lives. For example, older people are often excluded from admission to mental hospitals or are indiscriminately transferred from mental hospitals to unprepared communities without adequate services. The availability of services in community mental health centers is limited, and contact between the elderly and psychiatrists in private practice is minimal.

Age discrimination in hiring should be a thing of the past in the federal sector with the passage of new legislation (Public Law 95-256, April 6, 1978). Thanks to the efforts of Representative Claude Pepper (D.-Fla.), mandatory retirement no longer exists in the government, although reservations still exist in the private sector. These reservations mean that in some cases retirement is based on age rather than on competence, need, or desire to work.

Cultural prejudice is exemplified by the use of epithets such as "crock," "crone," and "old biddie." The medical profession has epithets of its own: "serum porcelain level," "turkey," and even "dirt ball." Social attitudes are painfully clear when the old are referred to as "out to pasture," "fading fast," "boring," and "garrulous."

The basis for ageism is personal dread and discomfort at the prospect of growing old, with its presumed concomitants of helplessness, pain, disability, and, ultimately, death. This fear is reinforced by our cultural emphasis on youth and productivity rather than experience and service.

Institutionalized efforts to treat or combat ageism include laws against age discrimination, the phasing out of mandatory retirement, and a return to the historically more common functional retirement based on individual capabilities. Self-education is essential. Much can be learned about the rich knowledge that accrues over the entire life cycle by listening to people review their lives from the special perspective of old age. Didactic reading in the biology of aging, human development, geriatric medicine, and geriatric psychiatry can be supplemented by a sampling of literature, for some of our greatest novelists have been attentive to the life cycle and old age. Cervantes (*Don Quixote*), Tolstoy

Dr. Butler is Director, National Institute on Aging, National Institutes of Health, U.S. Department of Health, Education, and Welfare, Bethesda, Md. 20014.

(*Resurrection*), and Shaw (*Back to Methuselah*) come immediately to mind.

Practical experience with patients in settings and under circumstances in which the possibility of effective treatment exists—for instance, in reversible depressions and the treatable reversible brain syndromes—can contribute much toward improving physicians' attitudes toward the old. Psychiatrists, who by virtue of their training are so well equipped to understand transference, can exploit their classic "bag of tricks" to examine and better understand themselves so as to come to terms with their own fears and dread of aging. Psychiatrists can, in fact, take leadership in working to overcome the general cultural negativism toward aging.

RESEARCH ON AGING

What can one hope to accomplish through research on aging? Should the ultimate goal be to extend life, or would this only serve to lengthen the period of decrepitude, depression, frailty, and mental, economic, and physical dependency? Remember the Greek legend of Tithonus, who was granted immortality but not eternal youth.

In establishing the National Institute on Aging (NIA) in the Research on Aging Act of 1974 (Public Law 93-296), the U.S. Congress chose to concentrate on the "alleviation of the problems of old age by extending the healthy, productive middle years of life." The NIA was created for the "conduct and support of biomedical, social, and behavioral research and training related to the aging process and the diseases and other special problems and needs of the aged" (Public Law 93-296, S775, May 31, 1974). Thus, in addition to the support of basic biological research, NIA is involved in studies of the body's great integrative systems—the central nervous system, the immune system, and the endocrine system—to understand better the nature and mechanisms of time-dependent processes such as declining immunity over the course of the life cycle. NIA is also interested in the behavioral nd social aspects of aging and supports studies of ma- psychological problems, sensory changes with age, life, and the differential life expectancy between es and among racial and ethnic groups.

The primary goal of NIA's research program is improvement in the quality of life. This research is not exotic or quixotic—it has clearly practical applications. For example, advances in our understanding of organic brain disease or the progressive loss of immune function would contribute to an increasingly healthy and more vigorous older population. (For more details on planned research in this area, see reference 1.)

Biomedical research at the National Institutes of Health (NIH) began in the 1930s with the study of specific diseases; it is only in the past 20 years that broad non-disease-oriented institutes have developed. Growing interest in behavioral medicine—for exa care and prevention—may shape future dev at NIH. The institutes' various approac study of human development, health, a make the possibility of collaboration intrigu stance, an improved understanding of the over time that appears to occur with agin vide a means to delay the onset, alter the tions, or reduce the severity of certain ag time-dependent diseases.

THE TRIUMPH OF AGE

The fact that so much is made of the lem" is itself an expression of a deep unde ambivalence toward growing old. It is true older people have problems, but this is the dramatic increase in the absolute number proportion of older people in this century. S not prepared for this "demographic revol problems evolved, but they are likely to be adaptations are made. Just as the geograph tion of the fifteenth and sixteenth centuries entific achievements of Newton and Darw tated vast changes in human thinking, so tions, education, industry, and the family, we adapt to the changing population struc

The demographic revolution is largely a r reductions in maternal, infant, and childhoo in Eastern and Western industrialized nati ity is increasingly limited to old age; ap 70%–80% of all deaths now occur after ag

At the time of the founding of the Amer lic, only 20% of newborn babies lived to be trast, approximately 80% now live to be hardly more than 4% of American familie three generations, despite the idealized days" version of the three-generation Am ily, complete with cookie-baking grandm pipe-smoking grandfathers. It is in this ca cause of increased survivorship, that the t tional and even multigenerational family more than a rarity.

In 1920, the chance of a 10-year-old's living grandparents was 40%; today, it is only 44% of women who survived beyond were likely to attain adulthood, marry, hav see those children leave home, spend some time with their husbands, be widowed, an old age. Thus, 56% did not experience the course" of the twentieth century (2).

It is certainly a triumph that this centur in which the opportunity to fulfill the lif been generally available. Life expectancy— tion of how many years an individual of a will live, based on existing actuarial da creased from 49 years in 1900 to 73 years span—the maximum inherent longevity, probably between 100 and 120 years

beings—has not been extended; rather, we have had a greater survivorship and a resulting increase in life expectancy.

NIA and other agencies and individuals involved in research on aging have the task of making it still more likely that people will have the opportunity to flesh out the totality of their life cycles. We need to understand better the 8-year discrepancy in life expectancy between men and women so that we can extend the life of men to the advantage of both. Currently, because of the poverty associated with widowhood, the average woman has about a 60% chance of becoming destitute. We must also examine the limited life expectancy of certain racial and ethnic groups.

We must remind ourselves that when we speak of aging we are not dealing with a problem but with the result of scientific and medical advances that allow more and more people to experience the last chapter—the consummation—of the life cycle.

PSYCHOLOGY OF AGING

Human developmental studies have historically focused only on children, although study of the aged provides a valuable counterpoint because the aged embody the outcome of these developmental processes. Biographies describe how certain people have lived their lives, but no one has systematically examined the entire human life cycle. We know too little about the psychology of the last years of life, and such knowledge would have practical applications. What traits increase survival? What features enable an individual to adapt better to the normal challenges and stresses of life, as well as to accidents and disability? The answers to such questions would not only help us improve the quality of life of the aged, they would also change our thinking about human development and provide new questions for those studying this process. Perhaps this would be the most effective answer to ageism: if we view the life cycle as a whole, if we see ourselves as of one cloth, we can begin to resolve the ambivalent and conflicting feelings that now prevail in relation to old age.

One means for psychiatrists to learn about the psychology of aging is to *listen* to older people review their lives. Life review is a natural process of reminiscence, during which the individual deals with past conflicts and tries to resolve problems. Psychiatrists who have avoided treating the elderly, dismissing their reminiscences as aimless or wandering, are missing a valuable opportunity to learn about the totality of life from those best qualified to discuss it. An added benefit is that the life review of an older person can help the psychiatrist confront and overcome his or her personal fears and denial of aging.

OUR FUTURE SELVES

Regrettably, some older people in society feel obliged to behave according to social expectations, i.e., to conform to society's norms or negative stereotypes. However, there are those in society who provide us with powerful models of what aging should be and of what effective aging is, for effective aging is not the same as aging graciously. Francis J. Braceland, M.D., is quite an extraordinary model from whom we can learn if we can permit ourselves to do so. New knowledge obtained through research on aging and the self-knowledge that comes from interactions with the aged could eradicate the social and personal pathology of ageism. One by-product would be a renewed appreciation of the significance of life, including the later years, of which Montaigne wrote so movingly:

> Especially at this moment, when I perceive that my life is so brief in time, I try to increase it in weight; I try to arrest the speed of its flight by the speed with which I grasp it, and to compensate for the haste of its ebb by my vigor in using it. The shorter my possession of life, the deeper and fuller I must make it.

Private Psychiatric Hospitals: "Excellence Is Their Watchword"

BY ROBERT W. GIBSON, M.D.

Throughout their history private psychiatric hospitals have been a major force in psychiatry, and their humanistic concern for the mentally ill has resulted in numerous innovations in treatment. Over the past two decades the sharp increase in psychiatric patient care episodes has resulted in a greater reliance on private psychiatric hospitals, and they have responded by modifying their role, broadening the spectrum of patients served, and developing alternatives to inpatient treatment. In addition to continuing to provide high-quality inpatient care, private psychiatric hospitals in the future should expand various alternatives to such care, explore opportunities for collaboration with other health care systems, and provide more patient services to the underserved.

ALTHOUGH private psychiatric hospitals accounted for only 3% of the total patient care episodes in 1975 (1) and have probably never provided more than 5% of that care, they have been and continue to be a major force in psychiatry. During the 1800s a small group of psychiatric hospitals, by their espousal of the moral treatment of the insane, were instrumental in bringing patients out of the almshouses, attics, and prisons. John S. Butler, M.D., who served from 1843 to 1873 as the fourth Superintendent of the Hartford Retreat (now the Institute of Living), was a leader in the movement toward humanitarian care of the mentally ill. Describing his visit in 1842, the year before Dr. Butler moved to the Hartford Retreat from the state hospital in Boston, Charles Dickens marveled that

> every patient in this asylum sits down to dinner every day with a knife and fork, and in the midst of them sits the gentleman [Butler] whose manner of dealing with the charges I have just described. . . . At every meal moral influence alone restrains the more violent among them from cutting the throats of the rest: but the effect of that influence is reduced to an absolute certainty and is found even as a measure of restraint to say nothing of it as a means of cure, a hundred times more efficacious than all the strait waistcoats, fetters, and handcuffs that ignorance, prejudice, and cruelty have manufactured since the creation of the world. (2, p. 87)

Dr. Gibson is Medical Director and Trustee, Sheppard and Enoch Pratt Hospital, Towson, Md. 21204.

In 1948, when Albert Deutsch wrote *The* [illegible] *the States* (3), this same humanistic con[illegible] private psychiatric hospitals provided [illegible] that the mentally ill deserved more than th[illegible] warehousing and neglect to which they were [illegible] gated. Some private psychiatric hospitals [illegible] major programs of research, and virtually [illegible] novators in applying the newly emerging [illegible] their treatment programs. As freestanding [illegible] training centers or in affiliation with acade[illegible] many private psychiatric hospitals offered [illegible] an opportunity to learn from intensive w[illegible] small number of patients under the tutelage [illegible] enced clinicians. As treatment services inc[illegible] patterns of care changed, private psychiatr[illegible] frequently in collaboration with newly dev[illegible] cilities, continued as models of excellence [illegible] to serving the patient. Guided by Francis J. [illegible] M.D., the Institute of Living continued to [illegible] standing example of excellence.

A CHANGING MENTAL HEALTH DEL[illegible] SYSTEM

Action for Mental Health (4), the repo[illegible] Commission on Mental Illness and Healt[illegible] to several important changes in health ca[illegible] during the past two decades: a significant [illegible] the number of psychiatric units in gener[illegible] the development of community mental he[illegible] with federal support, and sharp decreases [illegible] ber of beds in state and county mental ho[illegible] tient care episodes[1] more than quadruple[illegible] from 1.7 million episodes in 1955 to 6.9 mil[illegible] The rate of patient care episodes per 10[illegible] lation tripled, increasing from about 1,000 [illegible] 3,000 in 1975. Inpatient episodes accoun[illegible] of the total in 1955 but only 27% of the to[illegible] with 70% outpatient and 3% day treatment [illegible] episodes (1).

Despite these increases total admissions [illegible] care episodes still fall short of the estimate [illegible] its preliminary report of September 1977 (5, [illegible] dent's Commission on Mental Health est[illegible]

[1]Patient care episodes are defined as the number of [illegible] patient facilities at the beginning of the year (or the [illegible] sons on the roles of non-inpatient facilities) plus the [illegible] missions, readmissions, and returns from long-term [illegible] the year.

0002-953X/78/007A-0017$0.50 © 1978 American Psychiatric Association

"between 20 and 32 million Americans need some kind of mental health care at any one time" (p. 4). As a consequence,

> The current direct cost of providing mental health services is about $17 billion a year. The social cost, when measured in terms of lost wages and a shortened life span, is estimated to be another $20 billion. (p. 4)

And beyond these statistics,

> There are millions more who seek help for emotional problems elsewhere, especially from their personal physicians or from health care clinics. For example, 15 percent of patients seen in general medical practice are found to have psychiatric or emotional problems. At any given time, 25 percent of the population is under the kind of emotional stress that results in symptoms of depression or anxiety. (pp. 4–5)

The increase in patient care episodes should continue. The need is there, and progress is gradually being made to overcome the stigma that impedes the treatment of mental illness. The trend toward greater reliance on community mental health centers, general hospitals, and private psychiatric hospitals is appropriate. The financing of mental health care is grossly inadequate but is improving slowly. Improved financial resources should reduce the dependence on government institutions, and state mental health programs are making a deliberate effort to shift care toward the private sector. Private psychiatric hospitals are already modifying their role and can be expected to do so without compromising quality.

CHANGES IN PRIVATE PSYCHIATRIC HOSPITALS

Until 1972 the numbers of patients served by private psychiatric hospitals and the distribution between inpatient and outpatient services were relatively stable. Bethel (6) reported that during the period 1968–1971 the number of hospitals stayed at about 150. The number of inpatients in residence at year-end varied only from about 10,200 to 11,000; annual admissions fluctuated from a low of about 87,000 in 1970 to a high of 92,000 in 1969. Changes in the distribution of admission diagnoses were slight, with depressive disorders accounting for approximately 40% of the total and schizophrenic reactions for 20%. However, there was a trend toward the admission of younger patients; patients under age 25 at the time of admission constituted 18% of all admissions in 1968 and 24% in 1971.

Substantial changes began to occur during the period 1972–1975, when the number of hospitals increased to 180, the number of inpatients in residence at year-end rose 10% to about 11,500, and annual admissions rose to 130,000. The growth in the number of hospitals was due largely to new investor-owned hospitals. By 1975 nearly two-thirds of all private psychiatric hospitals were operated by corporations, individuals, or partnerships on a for-profit basis, with the other third operated by not-for-profit groups, including church foundations. The greatest number of hospitals and beds was concentrated in the mid-Atlantic region, with the smallest number in the Northwest. Private psychiatric hospitals in New England had the greatest number of beds per 100,000 U.S. resident population. About 15 states had no private psychiatric hospitals, and 11 states had only 1; California had 27, and New York had 14 (7).

Although private psychiatric hospitals are organized to provide inpatient care, alternatives to inpatient treatment are being developed. Between 1971 and 1975 admissions to private psychiatric hospital outpatient programs increased 80%, day treatment, 67%; and inpatient care, 44% (8). By 1975, of a total of about 180 private psychiatric hospitals, 42% provided day treatment; 35%, outpatient care; 24%, emergency services; and 8%, halfway houses (9).

CHARACTERISTICS OF THE PRIVATE PSYCHIATRIC HOSPITAL—1975

In an effort to clarify the role of the private psychiatric hospital in the mental health delivery system, the National Institute of Mental Health and the National Association of Private Psychiatric Hospitals jointly conducted a survey of one month's admissions to private psychiatric hospitals (10). This study yielded information from three-fourths of the hospitals surveyed, making it reasonably representative of the total. During May 1975, the month surveyed, 7,864 people were admitted to the inpatient services of 139 private psychiatric hospitals.

Of the total number of patients admitted, 42% had depressive disorders; 22% had schizophrenia; 9% had alcohol disorders; 6% had adjustment reactions of adolescence, adulthood, or late life; and 5% had personality disorders. The remaining 16% suffered from drug disorders, organic brain syndrome, childhood disorders, and neuroses excluding depressive states. About 45% of the patients admitted were male and 55% female. The trend toward younger patients continued, with 27% under 25 years of age, 37% aged 25–44, 27% aged 45–64, and 10% 65 years old or older (10).

The survey indicated that the three major referral sources of all inpatient admissions were private psychiatrists (44%), followed by self, family, or friends (24%) and by other physicians (11%). Approximately three-fourths of the patients admitted reported previous psychiatric care. Thirty-nine percent had received previous inpatient care in the same hospital to which they were admitted, and 30% had received inpatient care in another psychiatric hospital (10). About 3 out of 10 patients had seen private psychiatrists, and more than 1 out of 10 had had other types of noninpatient psychiatric care. This suggests that most of the patients admitted posed serious therapeutic prob-

lems and many had been treatment failures.

The types of psychiatric treatment most frequently received by the patients in the survey were individual psychotherapy (90%), drug therapy (83%), group psychotherapy (61%), family therapy (20%), and electroconvulsive therapy (8%). Ninety-four percent of the patients received two or more types of treatment, and about 70% received three or more types. The median number of days spent in the hospital was directly related to the number of treatments, presumably because of the greater severity of illness in those patients receiving multiple therapies. Patients receiving one type of treatment stayed a median of 8 days, two types 17 days, three types 21 days, four types 25 days, and five or more types 31 days (10).

Staff-patient ratios are too gross to be an indicator of the quality or adequacy of treatment programs. Many factors are not taken into account in such an index—for example, the patient mix in terms of age, diagnosis, or severity of condition, and the type and intensity of the program. Nevertheless, comparisons of staff-patient ratios for the various types of mental health facilities do illustrate major differences in the intensity of patient care and give some indication of the level of care in private psychiatric hospitals.

According to Taube and Witkin (11), in January 1974 the staff-patient ratio for all private mental hospitals in full-time equivalents of staff per 100 average resident patients was 204 total staff, with 124 patient-care staff (66 professional and 58 other). Not-for-profit private hospitals had a ratio of 238 total staff compared with 173 total staff in investor-owned hospitals; there were 140 patient-care staff in not-for-profit hospitals compared with 110 in investor-owned hospitals. Within the nonpublic general psychiatric hospital units the total number of staff per 100 patients was 130, with 115 patient-care staff (65 professional and 50 nonprofessional). In state and county mental hospitals the total staff per 100 patients was 88, with 57 patient-care staff (18 professional and 39 other).

Of the May 1975 admissions to private psychiatric hospitals, about 95% of the patients were discharged in 4 months or less. Over 90% of all patients were discharged within 12 weeks, with 23% in 7 days or less, 17% in 8–14 days, 25% in 15–28 days, 14% in 29–42 days, and 13% in 43–84 days. Of the patients discharged, about half had been referred to private psychiatrists for further treatment and one-fourth to outpatient psychiatric clinics or services (10).

In summary, about two-thirds of the patients admitted had depressive disorders or schizophrenia. Over half were referred by psychiatrists or other physicians and one-fourth by self, family, or friends. Most patients had had previous psychiatric treatment, often inpatient care. Psychotherapy (individual, group, and family) and drug therapy were the principal treatment modalities, with the vast majority receiving multiple therapies. Staff-patient ratios were generally higher in private psychiatric hospitals than in other mental health facilities, with the not-for-profit hospitals highest at 238 total staff and 140 patient-care staff [illegible] patients. About two-thirds of the patients [illegible] charged within 4 weeks and 90% within 12 [illegible] three-fourths referred for continued treatment

A PLURALISTIC SYSTEM

At this juncture there is no reason to believe that one type of facility is in all respects superior to another. Each has its strengths depending on the [illegible] and characteristics of the institution. For this [illegible] pluralistic approach is in order and will probably continue indefinitely. However, it is helpful to [illegible] the differences among facilities in order to [illegible] how each can best serve the patient.

In the psychiatric units of nonpublic general hospitals, inpatient services are stressed and about [illegible] the patient care episodes involve this treatment [illegible]. Treatment is usually short-term, with an emphasis on crisis resolution and reliance on somatic therapies. The ready availability of surgical and general medical services gives the psychiatric unit of the general hospital a particular advantage in the treatment of patients with interrelated physical illness, psychiatric complications of medical and surgical conditions, somatic psychosomatic illnesses, substance abuse requiring detoxification, and severe organic disorders. Because the attending psychiatrist can follow a patient through modes, including inpatient, outpatient, and [illegible] ment, continuity of care is enhanced. However, physical space, facilities for activities, and [illegible] treatment services are often limited, particularly in smaller units. Hospital support services designed for the needs of medical and surgical patients are not always well suited to the needs of psychiatric patients, particularly those requiring intermediate or [illegible] care. Daily costs are usually higher than in [illegible] hospitals, but this is offset by generally better third-party coverage. Some patients and families find treatment more acceptable in the psychiatric unit of a general hospital because these units are in the mainstream of the medical care system.

Community mental health centers place emphasis on outpatient and day treatment (about [illegible] 7%, respectively, of patient care episodes) [illegible] as alternatives to hospitalization. As an organized system of care, most provide at least the five services initially required for federal funding (emergency, outpatient, day treatment, emergency, and [illegible] tive services). They are expected to identify [illegible] the needs of the residents, particularly [illegible] served, within a defined catchment area and [illegible] for early and prompt intervention. There [illegible] liance on psychiatrists, with corresponding greater use of other mental health professionals and [illegible] professionals. Matching funds helped community mental health centers get started, but severe fiscal [illegible] have been created by the withdrawal of the funds. Somewhat belatedly, the centers are looking [illegible]

sources of financial support such as Blue Cross, commercial carriers, and personal payment.

State mental health systems, particularly state hospitals, have come under intense pressure as the cost of health care has escalated and budgets have not kept pace. This has caused an erosion of resources available to the hospitals and has provided only limited funds for new outpatient and day treatment services in the community. Deinstitutionalization programs all too often have been imposed by politicians with the intent of cutting costs rather than meeting the needs of patients. The leaders of many state mental health programs have recommended that rather than being direct providers of care, states should assume the initiative in identifying needs, planning, coordinating, determining priorities, setting standards, allocating resources, and evaluating. Despite the problems, many state programs are excellent. As direct providers of care the state systems potentially are in the best position to provide programs that fill needs not currently met by the private sector. In many instances these efforts can be enhanced by collaborative arrangements with private hospitals, general hospitals, and community mental health centers.

ROLE OF THE PRIVATE PSYCHIATRIC HOSPITAL

The main purpose of the private psychiatric hospital is to serve the patient. Many private hospitals, as collateral purposes, engage in teaching, research, and community consultation. Most private psychiatric hospitals strive for excellence that goes beyond simply meeting needs at an acceptable level of quality. As a consequence, they have, over the years, served as models against which to measure other programs.

In private psychiatric hospitals, treating the mentally ill is not simply one of many specialty services as it is in the general hospital. Even though private hospitals are expanding day treatment and outpatient programs, the emphasis continues to be on the inpatient treatment of individuals with severe psychiatric disorders, whereas community health centers stress emergency, crisis intervention, outpatient, and day treatment services. This allows the private psychiatric hospital to maintain programs to meet the needs of patients with more severe psychiatric disorders that require more specialized care.

Because of the emphasis on the treatment of psychiatric patients, the private psychiatric hospital is so organized that the institution becomes a therapeutic instrument in its own right. There has been a natural evolution from the moral treatment of the 1800s to the therapeutic community of the mid-1900s. The private psychiatric hospital provides the setting and resources for a coordinated treatment program in which most patients receive multiple therapeutic modalities. The potential is greater for definitive treatment beyond crisis intervention and symptom removal.

The private psychiatric hospital has an advantage over other types of facilities in preserving a direct relationship with the patient. A higher degree of confidentiality can be maintained despite the encroachment of some third-party payers and government requirements. The greater freedom of choice enhances the patient's capacity to develop a therapeutic alliance. The direct relationship to those they serve has made private psychiatric hospitals more directly accountable to the patient than is usually possible in large public systems dominated by the political process and government bureaucracy.

As part of the private sector, private psychiatric hospitals have relied on revenue from patient care as their major source of funding. Of the total admissions to private psychiatric hospitals in 1975, the principal sources of payment were as follows: Blue Cross, 37%; commercial insurance, 30%; Medicare, 11%; other types of government payment, 10%; and personal payment, only 6% (12). This reliance on revenues from services to patients has made private psychiatric hospitals cost conscious and has stimulated the development and refinement of management services. As part of the private sector, they have retained close ties with the majority of private psychiatrists, some 2,000 of whom serve as staff and resident psychiatrists, with several thousand more on attending or courtesy staffs.

Private psychiatric hospitals have struggled against such external regulation as the growing requirements of health planning, certification of need, and government third-party funding. The constraints are considerably greater than they were 10 years ago, but the private psychiatric hospital still has a greater flexibility and opportunity for self-determination than do most other psychiatric institutions. With its multiple funding sources, the private psychiatric hospital has greater latitude in responding to the dictates of third-party payers. Addressing the National Association of Private Psychiatric Hospitals, Dr. Braceland noted, "Government money is 'soft money,' and when economy programs are in vogue that money disappears just as government training and research money is disappearing now. Your hospitals are immune, for they should be dependent upon themselves" (13). Individually, and through areawide and national associations, private psychiatric hospitals have been vigorous advocates and effective leaders in influencing the funding policies of government and private insurers.

THE FUTURE

In the future, inpatient care of high quality for children, adolescents, and adults should continue as the hallmark of the private psychiatric hospital. Major expansions should be made in outpatient and day treatment programs. More specialized alternatives to inpatient care, such as halfway houses and community services, are needed. To be more accessible and responsive to community needs private psychiatric hospitals should initiate more diagnostic, evaluation,

emergency, and crisis intervention services. The spectrum of patients served should be broadened by greater emphasis on alcoholism programs, active treatment for the elderly, programs for the drug abuser, and special education for the mentally disabled. Greater involvement is needed in preventive programs of 1) consultation to community agencies, 2) public education, especially for those who influence others, such as executives, teachers, labor leaders, judges, and politicians, and 3) counseling, school guidance, and vocational rehabilitation.

Private psychiatric hospitals should participate actively in continuing education for mental health professionals and place greater emphasis on in-service training as a method of maintaining and improving the quality of psychiatric care. In keeping with their emphasis on excellence they should utilize, refine, and assess the new techniques for quality assurance. Private psychiatric hospitals can make significant contributions to research, particularly in the application and evaluation of newer therapeutic approaches. They should explore the opportunities for collaboration with public and private agencies, general hospitals, and state mental health systems, as well as with other organized health care systems such as health maintenance organizations and community mental health centers. As more resources are made available through government and private insurers, private psychiatric hospitals should strive to provide more patient services to the underserved.

As Dr. Braceland has so succinctly put it, "As to the future of the private mental hospitals, it is bright providing excellence is their watchword" (13).

History and the Psychiatrist

BY DAVID F. MUSTO, M.D.

Historical consciousness is a valuable tool in psychiatry. History can be useful to psychiatrists by expanding their awareness and revealing general errors in the content of psychiatric knowledge, detecting drastic distortions that appear in the ways knowledge is applied to patients, helping to avoid mistakes in public policies that involve psychiatry and result from erroneous impressions of social history, and alerting us to possible future trends. Although history does not give the answers—rather, a complex context within which to seek them—it still has value for the psychiatrist.

> If psychiatry is to take its proper place in the science of man, it must be aware of its limitations and realize that it is only a part of this science, an important but a small part insofar as the general knowledge of man is concerned. To forget this is to run the danger of scientific imperialism . . . the tendency, encountered regularly in the history of knowledge, to credit a special discipline with universal significance. The final result of such enthronement is always the catastrophic dethronement of the apparently supreme branch of knowledge. . . . The same danger faces psychiatry, if its popularizers become too enthusiastic or its enthusiasts become too popular.
>
> —Francis J. Braceland (1)

FRANCIS J. BRACELAND, M.D., exemplifies the observation that "great medical leaders [are] fully aware of the value of historical studies" (2, p. 32). He looks to history as a means for placing psychiatry in perspective and into the context of the rest of society, for overcoming what he called in 1945 "one of our difficulties in psychiatry . . . the tendency at times to operate in a vacuum" (3). He has examined the past with respect and humility. His respect arises from a deep interest in history as history as well as from the knowledge that the materials of history are so fragile and random that a preconceived form can be imposed on them which does not illuminate the present but becomes only one more self-serving element in contemporary controversy.

The understandable temptation to affect present policies and practices is likely to distort a historical account. Another cause of distortion is dogmatic certainty on the part of a psychiatrist or other student of history that he or she knows the answer to contemporary policy questions. For such individuals, the past becomes a storehouse of illuminating incidents, and convenient proofs are not difficult to extract from an otherwise complex collection of opinions and raw data. Theoretical or ideological certainty is a sure guide, and its possessor an assured investigator. Therefore, those who are certain of contemporary injustice—or justice—may search the past and easily believe they have found confirming evidence that they can label with the objective emblem of "history." At the very least, history is filled with usable anecdotes.

In the nineteenth century, history was adduced to prove, when taken with the certainty of clinical and "scientific" judgment, that the Irish or blacks were inherently inferior. In the twentieth century, historical evidence has been chosen to "prove" that psychiatry imprisons people and molds their behavior in order to assure social conformity. Of course, in the latter instance, "psychiatry" suffers from the same holistic interpretation that too often is applied to "history." For better or worse, there is no more a unified entity of "psychiatry" than there is one of "history"; beyond some broadly shared aims within each profession, the practitioners are disparate. Generalizations about either discipline are difficult.

When a psychiatrist approaches history without some sense of psychiatry's current limitations, psychiatry suffers as much as history. The opportunity to question contemporary assumptions, both practical and theoretical, is lost when the past is shaped with a heavy hand and tidy theoretical formulae are imposed on superficially familiar events. The assumption is that truth is to be found in contemporary knowledge—that contemporary beliefs are universally true and can be applied to events that took place in other times and places. With this confidence in ourselves and our times, to study history means merely to harmonize rules of behavior with chaotic bits of information.

A related assumption is that history, whether of psychiatry or not, is not relevant to decisions regarding psychiatric practice or policies today. All of the information and political wisdom required for the best pos-

Dr. Musto is Associate Professor of Psychiatry, Child Study Center, Yale University School of Medicine, 333 Cedar St., New Haven, Conn. 06510, and Associate Professor of History, Yale University Graduate School.

sible decisions is present in a narrow band of time extending back no farther than the lifespan of the eldest in a group or bureaucracy. To believe that the present day has the elements for answers to social problems is rarely a conscious rejection of history: it is more often a simple lack of awareness that prevents us from considering the past beyond our own memories.

More than most other medical specialties, psychiatry is closely entwined in the social and cultural mores of our era. Furthermore, the profession has not consistently demonstrated a self-reflective power to see clearly how it is influenced and, at times, severely distorted by forces within society. The failure to study the vicissitudes of psychiatry over time only diminishes awareness of how distortion may occur. Similarly, ignorance about cross-cultural psychiatry tends to overemphasize the importance of our own cultural expressions, leading us to perceive as universal those norms of behavior which are in fact characteristic only of our own place.

THE VALUES OF HISTORICAL PERSPECTIVE

To gain perspective on our own place and time is one of the values of a historical consciousness. Whether there is a more practical application depends on the issue addressed. Sometimes this perspective appears to be its own reward. At other times, history may delay or discourage action, although this is not necessarily an unfortunate result. As the late Richard Hofstadter cautioned, "History forces us to be aware not only of complexity but of defeat and failure: it tends to deny that high sense of expectation, that hope of ultimate and glorious triumph, that sustains good combatants. There may be comfort in it still" (4, p. 466).

In the last two decades there have been many studies that are models of sensitive reconstruction of psychiatric history, although not without application to the present. Prof. Gerald Grob of Rutgers University has published two studies, *The State and the Mentally Ill* (5) and *Mental Institutions in America* (6). Among several major contributions to the history of medicine and psychiatry are Prof. Charles Rosenberg's *The Trial of the Assassin Guiteau* (7), Norman Dain's *Concepts of Insanity in the United States, 1789–1865* (8), and Dain's later *Disordered Minds* (9). These books were written by professional historians, not psychiatrists. Along with other monographs they give evidence that those outside the psychiatric profession are becoming increasingly interested in the history of psychiatry and of the social history that embraces psychiatry. Although they deal primarily with the history of psychiatry, these studies are directed not just to psychiatrists but also to the public, policy makers, and, not infrequently, the most vociferous critics of psychiatry.

Historians' attraction to what not long ago would have been termed the history of psychiatry and the almost undisputed province of historically minded psychiatrists has been a mixed blessing. Just as [illegible] psychiatrists who have examined the past with preconceived ideological positions to attack or defend, so there are historians who have taken the past as a convenient collection of illustrations and "facts" with which to attack practices that they abhor in the present system or in psychiatric practice. Important critiques of psychiatry based on the past and written from psychiatrists include David Rothman's *Discovery of the Asylum* (10) and Michel Foucault's *Madness and Civilization* (11). Rothman, for example, sees a movement during the Jacksonian period to build institutions, such as asylums and prisons, as a means to impose conformity through rehabilitation in a controlled environment. Rothman sees invalid commitment of the deviant and dependent as growing, indeed a dominant, trend in the nineteenth century and into the twentieth century. The connection between this historical analysis and attacks on current procedures for psychiatric and criminal incarceration is obvious. What may at first seem an analysis of a distant period, maybe even a quaintly antiquarian study, becomes the basis for a broad attack on contemporary psychiatric practice and the conscious and unconscious intentions of psychiatrists.

Prof. Barbara Gutmann Rosenkrantz, another social historian, has criticized Rothman for a "failure to distinguish between intent and consequences" that leads to the conclusion that beneath a possibly disingenuous naïve reformist rhetoric lay a conscious repressive motive which, when balked, led to a conspiracy to control" (12). Criticisms such as Rothman's probably do not sound antiquarian to a psychiatrist today and are examples of the increasing importance of historical studies in defining psychiatry's role in our future. Psychiatry as a profession has a vested interest in preserving historical records and encouraging fair and thorough scholars to describe the past in detail and accurately. This desire for the best possible historical research is not just a humanistic altruistic joy in history as a pleasure in itself—it is also practical. Fine studies completed or underway by such psychiatrist-historians as Eric Carlson, George Mora, Henri Ellenberger, Otto Marx, and [illegible] Braceland (a fraction of those who could be named) have become a base for further social and professional histories of psychiatry in the United States. Psychiatric training, although it is not a prerequisite for research in psychiatric history, helps one to understand the problems and nature of psychiatric practice so that documents, articles, and other records can be more fully interpreted. Psychiatrists should make available their professional expertise to historians working in these fields.

The connection between the history of psychiatry and everyday practice and planning for the future of the profession may at times appear tenuous. However, the importance of a historical perspective in making decisions affecting psychiatry and the use of historical studies to define psychiatry's role in society and the

social issues with which psychiatry is associated are reasons that ought to impel any foresighted residency program to include courses in the history of psychiatry and American social history.

USEFULNESS OF HISTORY TO THE PSYCHIATRIST

History does not often provide specific answers to contemporary or future problems. When an answer to a problem has been found, it is not usually forgotten: penicillin is still popular for pneumococcal infections. The more common pattern is for solutions to recur and alternate, particularly when the problems cannot be or have not yet been solved. I suppose most of us will agree that we have a characteristic way of filtering incoming stimuli and limiting interpretations of the stimuli to a relatively few formulations. Within our own culture, explanations given for what has happened appear so reasonable that it does not seem necessary to worry about perceptions from another time or place.

History nudges us out of these adjustments to our surroundings, now and then to a useful extent. The occasions when a psychiatrist might find history useful can be categorized in at least four ways: 1) knowledge of the past can expand our awareness by revealing gross and general errors in the content of psychiatric knowledge, 2) drastic distortion can be detected in the accepted manner in which this knowledge is applied to patients, 3) false impressions of social history can result in errors in public policies involving psychiatrists, and 4) social and intellectual history is especially valuable today in alerting us to possible dangers we may face in the near future as psychiatry moves closer, for example, to biological determinism.

Examining Past Errors

Obvious errors in the content of psychiatric knowledge can be found in descriptions of social questions, minorities, and kinds of "mental illness" that rely for their authority on the clinical judgment and the special language of psychiatry—which is not, of course, to say that the record of psychiatry is one of consistent error. When psychiatry does err, at least when viewed in retrospect, the mistake frequently appears in confirming contemporary attitudes in the spirit of a neighborly social institution. Examples are found in the nineteenth century that are rarely debated by psychiatrists now. In the South, claims of inherent inferiority of blacks and the dangers to them of emancipation could be matched in the North by studies of Irish immigrants who were also claimed to suffer from a "constitutional inferiority" (13).

Dismissing these errors as being so far in the past that they are irrelevant to psychiatrists today would be to lose the value of uncovering these past beliefs. It is not that psychiatrists now have a responsibility for beliefs held in the past but that social conformity is a danger to the scientific role and task of psychiatry today. So far, no drug, treatment, program, or law has exempted the profession from the subtle and potentially dangerous effects of having one foot in science and the other in the marketplace. Although criticism from within and without the psychiatric profession is not currently lacking, sensitivity to distorting forces are better understood when the defensiveness and polemics of the issues have long passed. In this sense, the more temporally remote or the less relevant the subject matter of a historical study, the more useful may be the lesson to be learned for our own debates and motivations.

Dealing with Distortions

Some of the ways in which the consensus of psychiatric opinion has been false are documented by history; even the recent past gives evidence that the profession's usual standards of operation, the "delivery system" as we now term it, can undergo dramatic shifts under extreme political pressures. If there is one canon of psychiatric ethics held in the highest respect, it must be that of preserving confidentiality. Psychiatrists have gone to jail rather than reveal patients' statements. Psychiatrists' offices have been burglarized because people wanting information have recognized the hopelessness of obtaining it in any other way. Some psychiatrists keep almost no record of their patients' statements; others disguise their progress reports in an almost incomprehensible jargon. Yet, in the early 1950s, prominent psychotherapists did provide to an academically operated "Appeals of Communism Project" information on patients who had been members of the Communist Party (14).

The therapists were selected "by reputation, position, or published papers . . . in social science research" (14). Thirty-five cases were studied intensively and were provided by the therapists chosen in this responsible manner. About half the therapists declined to provide cases, but "whether their refusal was based on lack of pertinent case records or on lack of willingness to cooperate" (14) was unclear to the project's directors. There was no statement published indicating that these patients had consented to this use of their histories, although the published checklist of information requested from the therapists includes categories that would easily identify the patients to anyone knowledgeable about their party careers or public accomplishments. This request from competent and respected investigators must have been flattering, for the purpose was nothing less than to determine the family constellation that bred Communists and the defensive role of Communism in the lives of Communists. That the nation appeared to be in grave danger may have justified this apparent breach of confidentiality, which at a later time might seem strange. If we take this incident merely as another example of how we have progressed, we conveniently ignore the humbling continuity we have with the past.

The Influence of Social History

Moving from the history of psychiatric opinion and practice to a broader field that we might name "medical history" or "social history," many examples of inaccurate or inadequate accounts of the past that have affected later generations may be found or at least suspected. One example in drug abuse policy is the famous historical precedent of the British system. According to the most devout American believers in the British system, the British had a serious heroin addiction problem after World War I. The Dangerous Drug Act of 1920 was instituted and interpreted to permit the supply of heroin to those addicted. The contrast is often made with the reactionary United States, where prison sentences were being meted out to addicts, while in humanitarian Great Britain they were supplied with the drug. One of the American proponents of this system, Alfred R. Lindesmith, granted in 1947 that "at first glance it might seem that [the British System] would make opiates more available than they are now and lead to a spread of the habit (15, p. 205)." Professor Lindesmith went on to say that the opposite was the case.

In 1972, Brecher and the editors of *Consumer Reports* (16) supported this account of history in *Licit and Illicit Drugs*, and it acquired even more credibility because it was published as a Consumers' Union report. The results of providing heroin to addicts were described as magnificent: "By 1935, the United Kingdom reported to the League of Nations that there were only 700 addicts left in the entire country" (16, p. 121).

Having been educated in this belief, I found the reality to be a surprise. The first correction to what has become a traditional account in America is that the British did not enact the Dangerous Drug Act because of any heroin problem in the United Kingdom. The 1920 act was in response to Article 295 of the Versailles Treaty, which required enactment of narcotic control laws within 12 months from the coming into force of the Treaty; ratification of the Versailles Treaty would also simultaneously signify ratification of the Hague Opium Convention of 1912 (17). This origin would help explain the complaint made in Parliament that the Dangerous Drug Act was much more appropriate for America, where there was a serious narcotic problem, than for the United Kingdom.

Examining the records of the Rolleston Commission in London, I found no evidence of a heroin addiction epidemic or even recognition of a high level of heroin use. The United States, especially New York City, was seen as the example of serious heroin addiction. The records of the New York City Department of Health reveal that almost 5,000 heroin addicts were registered at the city clinic in 1919–1920. Their mean age was in the early 20s. The Rolleston Commission a few years later searched for heroin addicts in Britain who might be studied (18). The dusty documents and obscure journals did not support what I had been told and what I read in medical school or residency.

The British had accepted maintenance of h... addiction because there was so little addictio... United Kingdom, just as the United States h... until growing numbers of addicts alarmed the p... The details of each "system" and their beginn... velopment, and our memory of them cannot b... ciated or sketched in a short space. All that i... of the reader is to suppose that there were v... heroin addicts, hundreds at most, in Great B... the 1920s, but that the policy of giving some ... addicts legal heroin was believed, in another ... and in a later generation, as being the reaso... low numbers of addicts rather than the re... allowing some maintenance. Then consider ... specious explanation is given as an argument ... ing heroin easily and legally available in th... States for a population of addicts estima... minimum of 250,000.

Having granted the assumptions, the reade... agree, I trust, that whether this is true or not ... significance to American policies regardi... abuse. Yet I have had the impression, after ... quite a few accounts of the history of drug ab... cies, that the issue is so divisive and the propo... convinced of their positions that careful hist... search is bypassed for narratives the author ... must be true because they fit their own pref... answer to the drug problem. The firm conv... the truth is known does simplify historical in... tions; it may also destroy their value.

Using the Past to Deal with the Future

The last of the four ways in which study o... may benefit psychiatrists today is as a guide t... ture. That statement must be quickly qualifie... history does not foretell the future. It can, howe... sitize us to the issues, alternatives, and resu... have occurred in the past. For example, a ... threat to national security like that in the 195... probably again severely strain confidentiality b... physician and patient. A more likely candi... close study from historical analysis is the trend ... chiatry and other social sciences toward a gr... gree of biological determinism in interpreting ... ual and group behavior.

Hereditarian explanations for behavior ha... popular in the United States in the past; they w... dominant mode of explanation for scientists a... cians until well into this century. Research in ... netics and constitutional characteristics shou... prevented on the grounds that the conclusio... be misused, but there is great need to become ... the ways in which hereditarian theories can ... applied and overapplied. In the past, biologi... minism has proven exceptionally attractive t... therapists but, more importantly, to policy m... the public. Complex social questions are set... more easily when approached from either ... sively environmental or hereditarian perspe... add to other worries about the results of this ...

must note that psychiatry and the social sciences in America have been exquisitely susceptible to programs based on research, which indicates that final proof for their validity is just around the corner.

COMMENT

Reviewing the various ways in which history can be recommended to the psychiatrist, I recall again Richard Hofstadter's caution about expecting too much from the study of the past. As the examples I have given suggest, history does not so much provide eagerly sought answers as a more complex context in which to make decisions. There may be comfort in it still.

The Illusion of Simplicity: The Medical Model Revisited

BY HERBERT WEINER, M.D.

Traditional medical models have been found to be linear, restrictive, and oversimplified. Only a truly biological model, encompassing evolutionary as well as molecular and cellular biology, can account for the complex origins, forms, and effects of disease, which are illustrated by a discussion of hepatitis B and slow virus disease. An updated biological model of disease takes into account predisposition to disease, the timing and route of infection, multiple disease forms, variable adaptive response, and the role of social and cultural factors and views disease as a failure of adaptation in one or more systems. Its application to psychiatry is shown in a discussion of stress, bereavement, and separation.

FOR REASONS that resist explanation, psychiatry has once again asked for admittance into medicine. Over the years, psychiatry has repeatedly wandered off along paths that seem to many doctors as remote as exobiology is from terrestrial biology. These excursions into therapy for societies, the improvement of mental health or of international relations, and the diagnosis from afar of psychopathology in the body politic and politicians, for instance, seem premature, if not innocent, to the medical profession.

Therefore, psychiatrists are being called back to their origins: we must be doctors to our patients' minds and bodies, not to the ailing body politic. We are trained as biologists; we diagnose illness, and we care for the sick. We hope to alleviate suffering; occasionally we cure. These ancient concerns of physicians go far beyond the legal right to prescribe drugs, and many psychiatrists have never broken with this tradition. However, others have wished to discard—or at least go beyond—the traditional roles that society has assigned to them because they are discontented with the medical model.

TRADITIONAL MEDICAL MODELS

Recent discussions about the medical model (1–4) have generally not mentioned that there is no one model or have suggested that a new model is nee[illegible] The model usually referred and subscribed [illegible] infectious disease model of the pathogenes[illegible] ease. It states, in its outmoded form, that a [illegible] type of agent is *the* cause of a disease entity, [illegible] the pneumococcus causes pneumococcal pr[illegible] Recovery of the pneumococcus from a patie[illegible] injection into a laboratory animal reproduce[illegible] ease. We owe this model to Koch. It perva[illegible] medicine and seeks a full explanation of a di[illegible] the basis of a single cause, whether the caus[illegible] rial, genetic, viral, enzymatic, immunologic, [illegible] tritional, or psychological. In its most gene[illegible] states that most diseases can be explained o[illegible] of single causes: "Behind every twisted thr[illegible] twisted molecule."

We owe the second model—the cellular pa[illegible] model—to Virchow. In essence, it states th[illegible] is due to a material defect of the cells or orga[illegible] body. Usually this defect is thought to be [illegible] caused by some external agent or by some [illegible] erration of the intrinsic machinery of the ce[illegible] ample, the absence or structural alteration [illegible] zyme. In formal terms a functional model, it [illegible] that fascinates most physicians.

Most medical explanations of disease are [illegible] in nature. They tell us about the relationsh[illegible] cardiac output to pulmonary edema, but the[illegible] tell us why at a particular point the heart fai[illegible] er words, most explanations of the symp[illegible] signs of a disease (and the functional disturba[illegible] express) do not explain its antecedents. Fu[illegible] the disadvantage of an antecedent, or histo[illegible] planation is that it is descriptive and not pred[illegible] example, a variety of animal or plant spec[illegible] explained in part by a genetic mutation, but t[illegible] does not predict when a new mutation wil[illegible] model of disease should allow us to predict [illegible] risk for a particular disease as well as wh[illegible] what circumstances the predisposed perso[illegible] velop it. Minimally, a complete model of dis[illegible] to be functional, historical, and predictive.

The third traditional model is the diagno[illegible] of disease. Kety (5) has defined it as "a pro[illegible] moves from the recognition and palliation [illegible] toms to the characterization of a specific [illegible] which the etiology and pathogenesis are k[illegible] treatment is rational and specific." How[illegible] ideal situation does not occur in nature. As [illegible] edge increases, we are continually recogn[illegible]

Dr. Weiner is Professor of Psychiatry and Neuroscience, Albert Einstein College of Medicine, and Chairman, Department of Psychiatry, Montefiore Hospital and Medical Center, Albert Einstein College of Medicine, 111 East 210th St., Bronx, N.Y. 10467.

tiple subforms of every specific disease, although each has an invariant cellular pathology; for example, subforms of Graves' disease, essential hypertension, peptic duodenal ulcer, and gout exist. The distinctive lesions of these diseases, the phenotypes, have different etiological or pathogenetic antecedents. Some patients with gout have normal levels of serum uric acid, and elevations of serum uric acid do not invariably lead to gout. Elevations of serum uric acid are produced by separate and distinctive enzymatic mechanisms that produce increased purine biosynthesis by cells or by the enhanced reabsorption of uric acid by the kidney or by a combination of both. In addition, the successful treatment of a disease does not have to depend on knowledge of its etiology or pathogenesis. Therefore, one must conclude that the diagnostic model of disease is idealistic, not realistic.

The fourth traditional model of disease is the curative one, which derives directly from the infectious disease and the cellular pathological models: once we know the singular pathogenetic cause of a disease or its disturbed pathophysiology, we are in a position to develop and launch the magic, curative bullet. Successes in the treatment of infectious diseases and vitamin deficiencies have reinforced belief in this model, which carries with it the hope that eventually we will cure all diseases. But nature is subtle and ever-changing. Bacteria are capable of adapting to the magic bullet. Changing social mores may cause the gonococcus to acquire plasmid DNA from *Hemophilus* residing in the human mouth, thereby producing penicillinase and becoming resistant to penicillin. Once we have a cure, it may not be permanent. Furthermore, most diseases cannot be cured; at most, all the physician can do is relieve suffering, alleviate symptoms, and avoid harming the patient (50% of all illness today is iatrogenic). Indeed, the physician's relationship with the patient can be a powerful agent in the relief of suffering and of symptoms. In addition, the medical profession has traditionally had a deep resistance to prevention of disease.

For the purposes of this discussion, I shall confine myself to these four models, although there are others (e.g., McKeown's discussion [6] of the consequences of the educational model in medicine).

TRADITIONAL MEDICAL MODELS AND PSYCHIATRY

Each of the four models of disease has had its proponents and opponents in psychiatry. In the nineteenth century, the major psychiatric diseases were considered by many to be diseases of the brain. Early in this century, this belief was strongly reinforced by that most paradigmatic and interesting of all psychiatric disease—paretic neurosyphilis. Here confirmation was found of the infectious disease model when Schaudinn's pale spirochete was discovered in the brain. Specific therapies could be directed at it in the form of fever, the arsenicals, or penicillin. Lost in this oversimplification was the fact that the spirochete in its tertiary phase causes paretic neurosyphilis in some but tabetic neurosyphilis, aortitis, gummata of bone and skin, or no disease at all in others. Furthermore, the variable symptoms of paretic neurosyphilis taught many psychiatrists all of psychopathology. Nissl's criterion for the diagnosis of paretic neurosyphilis was the presence not only of the spirochete but also of lymphocytes in the perivascular spaces of the brain.

We still have no explanation of the various phenotypic expressions of tertiary syphilis. The variable symptomatology of paretic neurosyphilis is usually explained by the interaction of the disease with the host's "personality." Nissl's observation is generally explained by the fact that the spirochete occasions a response by immunocompetent lymphocytes.

This model of a classical psychiatric disease has impelled psychiatry to search continuously for the bacterial, molecular, enzymatic, viral, and metabolic cause of mental illness. In another form and at another level of organization, this model has explained most psychiatric disease and its symptoms on the basis of specific psychological conflicts. Hysterical symptoms, for example, are said to have at their roots unconscious sexual conflicts or memories. This psychoanalytic formulation does not differ conceptually from the concept of the infectious disease model; it is merely phrased in a different language. Freud's initial concept of the hysterical symptom was modeled after the identification of a pathopsychological factor, just as much of medicine seeks the explanation of disease in pathophysiological terms *after* disease onset. Later it was recognized that every symptom is multiply determined, and an important dimension—the developmental one—was added to our understanding of symptoms.

Objections to the Traditional Models

Freud (7) also added to our knowledge of the taxonomy of specific psychiatric disease, and of persons, by studying character structure. Gradually the line between the cluster of symptoms and the character structure of the patient has become obscured; a hysterical patient is said to be at risk for hysterical symptoms, and his or her suggestibility can be used to advantage to remove them. Persons in fact have symptoms and diseases, or, in the extreme extension of this view, no disease at all. Disease is seen by some as a way of "labeling" people pejoratively (8). Besides, the argument goes, people are infinitely variable; psychological polymorphism is limitless, so one cannot label people accurately. Diagnosis is fruitless, classification difficult. A variant of this viewpoint holds that the taxonomic label is irrelevant—did Freud not state that we are all at root motivated by the same biological drives? Individuals are all fundamentally the same, according to this view; their problems are in essence just varia-

tions on the same theme, rather than diseases, so that treatment should focus not on diagnosis but on the drive that produced the conflict.

In addition, the concept that diseases cannot be separated from the personality of their hosts is enshrined in literature and medicine. It reaches its height in the work of Dunbar (9), who extended this concept from psychiatric to many "medical" diseases. More recently, Friedman and Rosenman (10) used this framework to describe the personality type at risk for coronary artery disease. Such an individual, they contend, has a high time-urgency, is impatient and irritable, and has an inner sense of being under pressure. This person may also be characterized by certain physiological features (11) such as a higher blood platelet count in whole blood, a lessened decrease in intensity of platelet aggregation to norepinephrine during exercise, an altered lipoprotein pattern (consisting of an elevated β- to α-lipoprotein ratio), and elevated mean serum cholesterol and triglyceride levels. Underlying this attempt at correlation between personality characteristics and disease is the assumption that certain persons are predisposed to a disease by virtue of both their personality and their physiology. Dunbar's approach to the role of psychological factors in disease did not address itself either to questions about the initiation of a disease or to questions about the mechanisms set into operation at the onset of the disease and those that maintain the disease. Thus, the questions of when and why a hard-driving (and inwardly driven) executive develops an attack of angina pectoris or myocardial infarction remain unanswered by this approach.

In this intellectual debate, medicine and psychiatry have confronted each other. The former states that only cells have diseases, the latter that only persons have diseases. The truth is that persons may have diseased cells or altered physiological functions.

DISEASE AS A BIOLOGICAL PHENOMENON

Medicine and psychiatry have both overlooked the fact that disease is a biological phenomenon. Biology consists of two great complementary bodies of knowledge: molecular and cellular biology and evolutionary biology. The first concerns itself with the origins, components, and structures of living things; the second with the manner in which organisms and populations of organisms behave, interact, and communicate and how they live in and adapt to their natural and social environments. In the process of successful adaptation some organisms survive to reproduce (12, 13). By virtue of their variable genetic composition and adaptive capacities some are selected to survive and reproduce in particular environments. Selective advantage in some environments is afforded even to those whose genes produce a specific molecular alteration; for example, hemoglobin-S in its heterozygous form produces the sickle-cell trait. Individuals with this trait are more likely to resist infection with falci- laria. Therefore, in certain environments endows the phenotype with selective adva genetic disposition to form immunoglobu antibodies confers selective advantage by resistance to parasitic invasion that may ca In other environments that contain othe those endowed with the capacity to form bodies are at risk for bronchial asthma and ot gic diseases (14, 15). These examples sug polymorphism must be viewed from two perspectives—cellular-molecular and evolut

These two perspectives are paradoxical evolutionary vantage point, selective advan en to some by the structural abnormality o The physician tends to focus on the struct tion in hemoglobin-S; the biologist welco cause it endows its owner with a selective a The physician is biased toward viewing pa molecular terms, whereas the evolutionary regards the same phenomenon in terms of nism's fitness to survive and reproduce.

The biologist is also concerned with the cu just the natural, environment and with cult tion, during which information is transferred generation to the next by language and tra by genetic means. By cultural evolution I evolution of an organism or population that about by culture acting as the agent. Durin cess, the organism or population may adapt changes.

The Infectious Disease Model Revisited

Many psychiatrists have rejected the fou models of disease because they have fou ear, restrictive, and oversimplified. The tra fectious disease, cellular pathological, and models have so far been unsuccessful in schizophrenia. Nonetheless, a call has gone chiatrists to return to these traditional medi (1) or to develop a model that incorporates cal and social data in the traditional medica using a systems theoretical approach (2).

A third approach consists of the develop truly biological model of disease, one that in the deep insights of modern genetics, virolo nology, biochemistry, cellular biology, and physiology. However, these insights are n if they do not also incorporate and integra cepts of developmental and evolutionary b

Such integration of these two bodies of makes the classical, linear infectious disease adequate, but we can replace it with a se model that contains genetic, developmenta personal, and social elements and is well by the biology of the hepatitis B virus (16) virus diseases (17).

Hepatitis B Virus

There are millions of carriers of hepatit

The prevalence of the carrier state is high in the Philippines and in parts of Europe and low in the United States. The virus can be transmitted horizontally from one person to another in a variety of ways—by blood transfusion, sputum, fecal contamination, a break in the skin, and probably by a variety of insect vectors, such as mosquitoes and bed bugs. The virus may also be transmitted vertically; women with this form of viral hepatitis just before or during delivery or women who are carriers of the virus may pass it on to their children, who in turn become carriers. However, this mode of transmission occurs only in some populations.

Most people who have hepatitis B virus remain carriers and do not develop any of the variety of diseases associated with it. However, the carrier state sometimes produces subclinical disease and mild biochemical abnormalities of liver function tests. At other times, the carrier state is not characterized by any detectable abnormality, but it is associated with the ability to form an antibody against one component, the core of the virus, and with the persistence of that antibody and of another viral antigen in the bloodstream of the carrier. The ability of carriers to transmit the virus is probably genetically controlled; some carriers are able to form antibodies against a third antigenic component of the virus and so do not transmit the virus. On the other hand, the virus may not even contain this third component, in which case the risk of transmission is reduced.

The hepatitis B virus may cause or be associated with a variety of diseases: 1) acute hepatitis, from which the patient may recover or which may go on to 2) chronic hepatitis; 3) chronic hepatitis not preceded by acute hepatitis; 4) any of a variety of diseases associated with immunological abnormalities or deficiencies that may enhance the presence of the virus in the blood; 5) the depositing in small blood vessels of complexes formed by the antigens of the virus and the antibodies of the host; and 6) primary hepatic carcinoma. Several factors determine which disease a person develops. Blumberg (16) suggested that the age at which the person is infected is one such factor—infection in utero or in infancy may be conducive to the later development of hepatic carcinoma in some but not all persons. The form the clinical disease takes is determined in part by the antigenic properties of the virus, by the capacity of the host's immune system to "recognize," or not, the foreign nature of the antigen, by the host's ability to develop antibodies against two, if not three, antigens of the hepatitis B virus, and by the timing and persistence of the antibody response.

Characteristics of Slow Virus Diseases

In some slow virus diseases—e.g., kuru and scrapie—the host does not respond at all immunologically to the unconventional virus and no inflammatory response is observed. Other slow virus diseases, such as subacute sclerosing panencephalitis, are caused by conventional viruses. In this disease the inciting agent, the measles virus, is defective; in other conventional slow virus diseases the host is immunologically defective.

Diseases produced by viruses also exemplify the oversimplification of the traditional cellular pathological model. The disease lymphocytic choriomeningitis, although incited by a virus, is characterized by the invasion of the meninges by a profusion of lymphocytes, as its name implies. However, no virus can be recovered from the brain or its coverings. The immunological response to the virus, present elsewhere in the body, produces the main lesion. If the virus is first injected into a pregnant animal, offspring later injected with the same virus do not show any invasion of the meninges by lymphocytes.

The developmental principle—that the kind of lesion produced by a virus depends on the age at which the animal is injected with it—is also illustrated by studies of immunological tolerance. If embryos of a particular strain are inoculated with various antigens, such as blood or other cells, from another strain, the adult will be tolerant to these foreign cells. At the time of later challenge, the antigenic substances are accepted as if they belonged to the recipient, a phenomenon that would not occur if the same antigens were injected into the unprepared adult animal (18).

The biology of lymphocytic choriomeningitis and of immune tolerance exemplifies the importance of the age at which the challenge occurs. When newborn mice are infected with the scrapie virus, no disease develops immediately. The virus does not replicate in these mice for 1 year, but when they are 18 months old, high titers of the virus are present in their brains and spleens. When mice are injected at 4 days of age or older, virus replication occurs immediately and kills 70%–100% by the time they are 10 months old (19).

Implications for the Disease Model

These viruses exemplify important biological principles in disease: the role of the host's genetic makeup in determining its adaptive (immunological) response, the host's age at the time of challenge by the infectious agent, and various interactions, from none to excessive, between the virus and the host's immune response to it. The biology of viruses and their interactions with the host have additional, even more interesting properties. Blumberg (16) stated that in "the epidemiology of infectious agents not only the host and virus are factors but also the previous host or hosts of the agent." The previous host may be human or, possibly, an insect.

Virus infections may also have surprising social determinants and consequences. Parental infection with hepatitis B virus may determine the sex ratio of offspring. If either parent is a carrier of hepatitis B virus and its surface antigen, more boys are born (20), but if a carrier parent has developed an antibody against the virus, fewer boys are born. Therefore, the virus may

partially determine the composition of a population and have effects on its economy and social structure and on the availability of marital partners.

Another major insight that modern virology has provided is that the customs of a social group may determine viral infection with a deadly disease. This in turn may determine the male-to-female ratio in a population (17). Kuru is rare in men but common in boys, girls, and women. Because it is a fatal disease, men predominate in villages where kuru is indigenous. Women and children used to mourn the deaths of their kin by engaging in the preparation and later ritual cannibalism of the infected brain of the departed and thus later developed kuru. With the abolition of cannibalism, kuru is declining in New Guinea.

The modern biology of virus infections therefore provides remarkable insights into the nature of disease. The model outlined is complex, nonlinear, and broad compared to the traditional infectious disease model. This new model is realistic rather than idealistic and has implications for our conceptualization of many other diseases. In summary, it states that

1. A pool of persons predisposed to a disease occurs in every population—the carriers.
2. The time of life a person is infected and the route of infection determine in part the course and nature of the disease or carrier state.
3. The same inciting agent can give rise to multiple disease forms, which are determined by the characteristics of the agent in interaction with the host.
4. The adaptation (immune response) to the agent can vary quantitatively or qualitatively.
5. The different adaptive responses determine in part the ultimate form in which the disease is expressed.
6. Social and cultural factors play a role in disease and are in turn influenced by it.
7. The disease can be transmitted horizontally and vertically in several ways.

We can make some generalizations on the basis of these conclusions. For example, the factors that predispose to a disease are not invariantly those which incite or sustain it (21). In addition, in every disease genetic polymorphism plays a complex role. The age and sex of individuals determines their response to disease. The phenotypic expression of disease is a complex product of the interaction of the agent and the host in which qualitative and quantitative variables in the adaptive-defensive responses of the host play significant roles.

THE NEW INFECTIOUS DISEASE MODEL AND THE BIOLOGY OF DISEASE

Our present understanding of the role that social, cultural, and behavioral factors play in disease is startlingly analogous to the generalizations outlined in the previous section. If biology is also viewed in evolutionary and cultural, rather than in only molecular and cellular, terms, then social, cultural, and b[illegible] factors can be incorporated into a biology c[illegible] Stress is no longer regarded in the linear [illegible] infectious disease once was. Stress, as a fac[illegible] inception of disease, produces response[illegible] stressed person that are signaled, if at all, by [illegible] The meaning of the stress may be portentous [illegible] if portentous it generates adaptive-coping de[illegible] person may flee, meet the challenge of the [illegible] overcome it, or be defeated by it. Success [illegible] with the stressful challenge is assured in pa[illegible] sonal factors such as intelligence, proble[illegible] ability, past mastery of the stress, and the [illegible] information available (22).

In some persons failure to overcome the [illegible] lead to helplessness, hopelessness, and giv[illegible] i.e., a state of adaptive failure. In others the [illegible] to stress, change, or challenge may be inapp[illegible] excessive. Some persons cannot cope with [illegible] events without another person's assistance. [illegible] immature, or adaptively inept, the person is [illegible] capable he is of coping alone or appropriatel[illegible] stronger the influence of the social field on [illegible] Other persons cannot cope because they are [illegible] of apperceiving or recognizing distress signa[illegible] ing that they should or must cope (25). [illegible] stress alone does not linearly produce disease [illegible] does so in interaction with the meaning it ha[illegible] stressed person, his manner of coping with [illegible] adaptive capacities. This principle is analog[illegible] homologous, to the interaction of a virus [illegible] adaptive-immune response.

In addition, today we know that the same [illegible] gous stresses or events can place people at [illegible] variety of different diseases. The stress of be[illegible] traffic controller is associated with an inc[illegible] cidence of elevated blood pressure, peptic [illegible] ulcer, and, sometimes, diabetes mellitus [illegible] reavement that is not coped with and pro[illegible] "giving-up, given-up" complex has been es[illegible] precede many different diseases (23). Ber[illegible] plays an important role in many, if not al[illegible] with "psychosomatic" diseases. Real or t[illegible] loss has often been cited as a factor contribu[illegible] initiation of other diseases as well (27): cance[illegible] tuberculosis (31), diabetes mellitus (32), l[illegible] and leukemias (33), juvenile diabetes mellitus [illegible] heart failure (35). Depressive moods, the [illegible] giving-up, and the loss of all hope also adver[illegible] the outcome of surgical operations (36, 37).

Therefore, it is not the bereavement per [illegible] termines the nature of the disease, any mor[illegible] hepatitis B virus is associated with any on[illegible] Bereavement may elicit a disease only in [illegible] disposed to it. In other persons a parting do[illegible] duce any disease but occasions appropriate [illegible] sorrow.

Separation early in life may also place org[illegible] risk for disease in later life. Separation has be[illegible] to produce alterations in the physiology and [illegible]

istry of the brain and in behavior. Every organ system so far studied is affected by the separation of young animals from their mothers; heart and respiratory rates fall (38–40), and levels of brain catecholamines, nucleoproteins, and enzymes such as ornithine decarboxylase diminish (41, 42). The prematurely weaned rat is at inordinate risk for later gastric ulceration when restrained (43), and the intrinsic physiological development of the stomach is altered by premature separation (S.H. Ackerman, personal communication). Premature separation also engenders a latent regulatory disturbance in the animal that is only elicited by later restraint-stress. This regulatory disturbance consists of the animal's inability to maintain its body temperature, which is highly correlated with the production of gastric ulcers (44).

The developmental principle that is exemplified by viral diseases and immune tolerance is also illustrated by these studies on stress. It may be extended even further, for it is entirely possible that some diseases are related to the persistence of, or reversion to, age-inappropriate (immature) regulatory patterns. In anorexia nervosa, age-inappropriate patterns of the luteinizing hormone have been found (45), and Vaillant (46) documented that age-inappropriate psychological coping patterns are significantly correlated with morbidity and mortality.

The principle that a virus disease can be transmitted vertically—that an acquired characteristic is "inherited"—is also illustrated by the observation that the offspring of prematurely weaned animals raised to maturity are at increased risk for gastric ulceration when later restrained, despite the fact that they were not prematurely weaned. The risk is much greater than in the offspring of a normally weaned mother (47). We do not know the nature of this effect; however, genetic transmission is highly unlikely.

SUMMARY

I have tried to illustrate that a broad biological model—not an outdated medical or narrow cellular or molecular model—incorporates observations and experimental data from levels of organization as diverse as the cultural, evolutionary, and molecular. In this framework disease can be viewed as a failure of adaptation that may occur in one or many systems; it is a biological phenomenon. Because it is a biological phenomenon, it deals with organisms in interaction with their natural, social, and cultural environments. Disease is not only a matter of a disturbance of the self-regulatory mechanisms within cells or of any one simple factor such as infection, nutritional deprivation, or the psychology of the diseased person. A modern, biological model of disease contains elements with which psychiatrists have often concerned themselves and is broad enough to accommodate diverse points of view from the molecular to the evolutionary level.

LOST IN A MAZE OF BEWILDERING THOUGHTS

'STELAZINE' HELPS FIND THE WAY BACK

The schizophrenic patient is often lost in a maze of bewildering thoughts, confusing voices and frightening anxiety. For such patients, 'Stelazine' provides effective control of these and other psychotic symptoms.

And 'Stelazine' can help patients participate in your therapeutic programs. Also important, convenient b.i.d. 'Stelazine' usually does not cause excessive sedation.

After 18 years of extensive research and clinical experience, no other antipsychotic agent has demonstrated significantly greater overall effectiveness and significantly fewer side effects than 'Stelazine'. These facts make 'Stelazine' a first choice for therapy.

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Generally avoid using in patients hypersensitive (e.g., blood dyscrasias, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only), 10 mg./ml.

IMPORTANT BOOKS FROM VAN NOSTRAND REINHOLD

NEUROSES: A Comprehensive and Critical View. *By Melvin Gray, M.D.* This broad and authoritative overview of the neuroses fills a serious gap in the literature of psychiatry. Surveying neurotic diseases from historical, philosophical, and clinical perspectives, it organizes a vast amount of information into a useful and coherent framework. Dr. Gray clarifies terminology, provides a practical method of organizing data for diagnostic purposes, and brings a balanced perspective to controversial issues in classification. He defines and discusses each of the eight neurotic diseases with regard to history, classification, etiology, diagnosis, differential diagnosis, course, prognosis, and treatment. "A monument to excellence and a trustworthy reference book . . . a powerful stimulation for research."—*From the Foreword by Roy R. Grinker, Sr., M.D. 1978, 341 pp., 6 x 9, $15.95*

PSYCHOPHARMACOLOGY: A Biochemical and Behavioral Approach. *By Lewis S. Seiden, Ph.D., and Linda A. Dykstra, Ph.D.* Current information on psychopharmacological research at the behavioral and biochemical levels of analysis. Drugs covered include the psychomotor stimulants, antidepressants, antianxiety agents, antipsychotics, analgesics, and hallucinogens. "Authoritative, concise, and comprehensive."—*Journal of the American Medical Association. 1977, 451 pp., illus., 6 x 9, $22.50*

THE THERAPIST'S HANDBOOK: Treatment Methods of Mental Disorders. *Edited by Benjamin B. Wolman, Ph.D.* Twenty-eight distinguished contributors describe and evaluate the major therapeutic techniques currently available. From clinical information on drug and convulsive therapy to research results concerning preventive mental health measures, they cover every important area in the field. "Authoritative, complete, practical, up-to-date . . . a credit to its veteran editor."—*Henry Brill, M.D., New York Department of Mental Hygiene. 1976, 556 pp., 6 x 9, $22.50*

ECOLOGIC-BIOCHEMICAL APPROACHES TO TREATMENT OF DELINQUENTS AND CRIMINALS. *Edited by Leonard J. Hippchen, Ph.D.* In this important work 21 contributing authorities from psychiatry, criminology, biochemistry, and related disciplines explore promising new treatment methods from the emerging field of orthomolecular psychiatry. They examine the theoretical basis of orthomolecular techniques and the latest developments in correcting such crime-related disorders as alcoholism, learning disabilities, and hyperactivity. *1978, 412 pp., illus., 6 x 9, $16.95*

HANDBOOK OF THE PSYCHOLOGY OF AGING. *Edited by James E. Birren, Ph.D. and K. Warner Schaie, Ph.D.* From primary sensory phenomena to personality and behavior deviation, this volume covers all important aspects of the psychology of aging. Twenty-nine outstanding contributors thoroughly examine the changes in behavior and capabilities that occur with advancing age. *1976, 740 pp., illus., 7 x 10, $33.50*

THE CHILDHOOD EMOTIONAL PATTERN: The Key to Personality, Its Disorders and Therapy. *By Leon J. Saul, M.D.* Singles out the childhood emotional pattern for intensive, goal-conscious study. It enables the therapist to discern the patterns, relate them to specific adult behavior, and use this understanding therapeutically. "Gives us a precise and intimate view of the transactions between patient and therapist . . . the author's skill is extraordinary."—*American Journal of Psychiatry. 1977, 323 pp., 6 x 9, $15.95*

THE CHILDHOOD EMOTIONAL PATTERN AND COREY JONES: A Psychoanalytic Biography. *By Leon J. Saul, M.D.* A prominent psychoanalyst and author traces the emotional development of a fellow psychiatrist over the course of his long, productive life. *1977, 336 pp., 6 x 9, $13.95*

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, and are not being considered for publication elsewhere. Papers with multiple authors are reviewed with the assumption that all authors have approved them.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. All submissions must be accompanied by a cover letter *signed by all authors* and using the following wording:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. The cover letter in such cases should contain the following wording and should be signed by all authors:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 2–3 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by the appropriate cover letter, including the copyright transfer statement, will not be reviewed until such a statement is received.

Authors will be notified as soon as possible of the receipt of their paper; at this time, the paper will be assigned a number that must be included in all further correspondence. It is imperative that authors of papers under consideration notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in *final form*, i.e., are ready for review. Authors must *not* submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions, and not all papers can be published in the *Journal*. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; this number must appear in any further communications about the paper. The copyright transfer statement described above must accompany annual meeting papers submitted for review.

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent, including references, tables, and figures (about 15 manuscript pages). Brief Communications—2,500 words or equivalent (about 10 manuscript pages). Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures can be used in this section). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 25 double-spaced pages (about 7,500 words) and should have no more than 100 references. All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures or references, etc. Single case reports will not be accepted as regular articles or Brief Communications; these papers should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and *no figures*) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular or Brief Communication length (a "prompt publication policy" is automatically in effect for Clinical and Research Reports). These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality, and authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed *double-spaced* throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review or listing may be sent directly to the Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Book reviews are usually solicited by the editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer. Reviews are usually less than 500 words long, seldom contain references, and will be edited.

TYPING AND ARRANGING THE PAPER

All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) *nonerasable* bond paper. All parts of the manuscript, including case reports, quotations, references, and tables, must be double-spaced throughout. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Please include degrees (other than honorary or undergraduate) after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. The authors' position titles and affiliations should be given in a paragraph using complete sentences. A full address is necessary only for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications (no précis is used in the Clinical and Research Reports section). The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material; a complete review of the literature is rarely desirable. *Accuracy of citation is the author's responsibility.* References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do *not* arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below and on the next page, double-spaced *throughout* (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26

2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information available in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit use for educational purposes or of an author who wishes to reprint his/her own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Reprint orders from others should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The American Journal of Psychiatry

will feature

● . . Psychiatry and the Third Party
By Paul Chodoff

Hallucinations... delusions... thought disorders... controlled

Navane (thiothixene) rapidly controls hallucinations as well as the agitation and hostility patterns they frequently generate.

Rapid control of psychotic symptoms on admission

Navane provides effective, rapid control of the major symptoms of psychosis including hallucinations, delusions, agitation, hostility, and thought disorders.[1-5] Navane promotes rapid progress, usually without the over-sedation or cardiovascular problems that can impede the therapeutic course.

Continued long-term improvement

Because Navane provides long-term outpatient control of psychotic symptoms, it can enable many patients to function effectively at home and on the job and to adjust rapidly to the community.[6]

Effectiveness rarely compromised by adverse reactions

Navane allows patients to remain alert and active, seldom causing over-sedation or drowsiness.[7] Hypotension and other cardiovascular reactions[5,6,8] are seldom reported and the occurrence of unpleasant anticholinergic side effects such as dry mouth or constipation is rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled through dosage adjustments or antiparkinson agents.

Rapid control
Long-term improvement

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml. Intramuscular 2 mg./ml.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

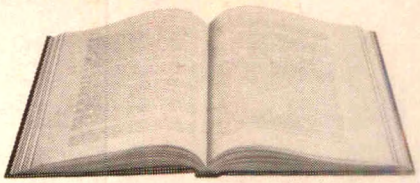
A PSYCHIATRY BOARD (PART II) REVIEW
OCT. 22, 1978

A one-day preparatory review
Under The Direction Of
Gerald H. Flamm, M.D.

The workshop, to prepare psychiatrists for the American Board of Psychiatry and Neurology Oral Examinations (Part II), will be conducted by Board Certified Yale Faculty. The emphasis will be on practical information to assist the candidate in understanding the format and objectives of the examination.

Each participant will have an opportunity to view simulations of both the clinical and video components of the examination. Candidates will also be instructed on optimal approaches to observing and discerning the critical elements from the video sections, both in Psychiatry and Neurology. The design of the workshop will permit each candidate to thoroughly understand the Board procedure for each of the three examinations.



The tuition for the one-day course is $125. All sessions will be held at the Yale School of Medicine. Luncheon will be provided.

The Yale University School of Medicine certifies that this Continuing Medical Education offering meets the criteria for 8 credit hours in Category I of The Physician's Recognition Award of the American Medical Association.

Registration information (i.e., name, address, telephone number) should be sent along with a check, made payable to the "Yale School of Medicine" to:

YALE UNIVERSITY SCHOOL OF MEDICINE
Department of Psychiatry — Continuing Education Program
34 Park St., Room 160, New Haven, Connecticut 06510

Withdrawals: Partial refund will be given when written notice is received at least one week prior the course. No refund will be made thereafter.

THE PSYCHOPATH IN SOCIETY

By ROBERT J. SMITH
A Volume in the PERSONALITY AND PSYCHOPATHOLOGY Series

FROM THE PREFACE:

It is precisely because the psychopath so defies our traditional mental (un)health categories —yet persists and even grows as a problem for society—that his existence creates such a challenge for the theorist and diagnostician. I propose here to look at Western culture at large in an effort to shed light on this phenomenon . . .

It is my intent and hope that this book will not only bring a fresh perspective to the study of psychopathy—and thereby be of interest to the professional mental health worker and theorist —but also be of sufficient timeliness and interest to engage a lay reader as well. . . .

CONTENTS: The Evolving Definition of the Psychopath: An Example of the Sociology of Science. The Charm and Winning Ways of the Psychopath. The Search for a Constitutional Explanation. Social Role Learning Theory Formulations of Psychopathy. Cleckley and the Psychopath. Psychopathy: Qualitative or Quantitative Entity? The Philosophy of the Marketplace and Psychopathy. Psychopathy in Varied Cultures. Psychopathy and the Future.

1978, 176 pp., $12.00/£7.80 ISBN: 0-12-652550-1

PERSONAL CONSTRUCT THEORY 1977

Edited by FAY FRANSELLA

Presented here are papers given at the Second International Congress on Personal Construct Theory held in Oxford in July 1977. The selected papers illustrate the imaginative ways in which the personal construct psychological approach has been used in a variety of settings. The range of topics is wide, some emphasizing theory, some applications and others development in grid technique. Since all the papers at the Congress could not be published in one volume, the papers selected for presentation reflect the following criteria: that readers would not have easy access to related work of the authors; topic areas should be as varied as possible; there should be an emphasis on research work. Abstracts of all other contributions to the Congress are included to indicate the wide range of interests of personal construct psychologists.

For depressed patients who must function effectively in daily activities...

PAMELOR®
(nortriptyline HCl) NF
25 mg·Capsules

Patients remain alert.

Most depressed patients must function effectively in their daily activities, on the job or at home. For these patients, PAMELOR capsules may be an appropriate therapeutic choice. PAMELOR relieves depression, yet rarely causes daytime drowsiness. As with all antidepressants, however, patients should be cautioned against driving or operating hazardous machinery.

Insomnia of depression begins to improve within a week.

PAMELOR capsules are effective for relieving insomnia, a cardinal symptom of depressive illness. Patients begin to sleep better within the first week of therapy. The full therapeutic effect of PAMELOR is usually observed by the second week.

PAMELOR therapy is well tolerated.

In 90 studies, a total of 818 patients were treated with PAMELOR capsules. Of the patients who improved completely or markedly, over half (54%) had no side effects. Those who experienced side effects most commonly complained of dry mouth.

For Brief Summary please see last page of this advertisement.

SANDOZ
PHARMACEUTICALS
EAST HANOVER, N.J. 07936

PAMELOR®
(nortriptyline HCl) NF
25 mg. Capsules

The antidepressant for the patient who must remain alert and active.

- relieves depression without causing problem daytime drowsiness
- insomnia of depression begins to improve within a week
- PAMELOR therapy is well tolerated

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Dosage and Administration: *Usual adult dose* – 25 mg. three or four times daily; dosage should begin at a low level and increase as required. As an alternate regimen, the total daily dosage may be given once-a-day. *Elderly and Adolescent* - 30 to 50 mg. per day, in divided doses, or the total dosage may be given once-a-day. Doses above 100 mg. per day and use in children are not recommended. If a patient develops minor side effects, the dosage should be reduced. The drug should be discontinued promptly if adverse effects of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution 10 mg./5 cc.

Theory and Problems of Adolescent Development

SECOND EDITION

By DAVID P. AUSUBEL, M.D., Ph.D.,
RAYMOND MONTEMAYOR, Ph.D.,
and PERGROUHI (NAJARIAN) SVAJIAN, Ph.D.

The Second Edition of this standard text has been thoroughly revised and expanded to reflect the developmental differences in American adolescence over the past quarter-century. The professional literature of the past 25 years has been exhaustively reviewed, and all noteworthy new materials have been included. The authors explain adolescence in the United States as a particular cultural variant of a pancultural stage in personality development that has universal attributes. They describe American adolescents in terms of their actual behavior in the middle 1970s, clarifying changes in sex role differences, attitudes toward parents, peers, school, vocational life, drugs, and sex mores. Chapters on cognitive, sexual, and moral development have been extensively revised and enlarged, and greater attention is paid to juvenile delinquency in middle class groups. The book presents a unified theory of a transitional stage of personality development that applies to teen-agers in all cultures.

1977, 576 pp., $19.50/£13.85 ISBN: 0-8089-1031-0

Ego Psychology and Mental Disorder

A DEVELOPMENTAL APPROACH TO PSYCHOPATHOLOGY

By DAVID P. AUSUBEL, M.D., Ph.D.
and DANIEL KIRK, Ph.D.

The purpose of this book is to provide a theoretical basis for "normal" personality development, and a basis for understanding "abnormal" personality development. It identifies and delineates significant variables influencing ego development, and its critical stages. Significant features of the book include: moral development is treated as an aspect of ego development; the nature, development and complications of anxiety are considered as consequences of aberrant ego development; ego development is traced from infancy to senescence; a special chapter focuses on black ego development; parent attitudes are considered exhaustively as determinants of ego development, including maternal and paternal deprivation; other approaches to ego development and psychopathology are compared and discussed.

1977, 368 pp., $19.50/£13.85 ISBN: 0-8089-1004-3

Responsive to therapy...

alert on the job.*

Haldol®
(haloperidol)
tablets/concentrate/injection

For long-term management of psychotic patients... with minimal risk of adverse effects

Highly effective in a wide range of acute and chronic psychotic disorders[1-7]

Permits aggressive titration to effective dosage levels for optimal control[1,4]

Usually leaves patients alert and responsive...
easier to reach with supportive measures[1-3]

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects[3-5,7-9]
Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Common side effects easily controlled[1,3-7]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

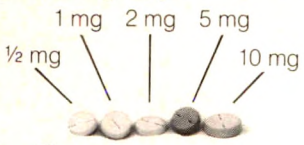
concentrate

A tasteless, odorless, colorless liquid concentrate for better patient compliance: 2 mg per ml.



injection

A rapid-acting injection for psychiatric emergencies: 5 mg per ml,* with 1.8 mg methylparaben and 0.2 mg propylparaben per ml, and lactic acid for pH adjustment to 3.4 ± 0.2.

tablets

5 tablet strengths for convenience in individualizing dosage:

HALDOL® (haloperidol)

tablets / concentrate / injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.

CHARLES C THOMAS · PUBLISHER

COUNSELING PARENTS OF THE MENTALLY RETARDED: A Sourcebook (3rd Ptg.) *compiled and edited by* **Robert L. Noland.** The editor presents information specifically directed at the counseling of parents of mentally retarded individuals, including the crucial issue of counseling at the time the parents are first told of their child's deficiency. *'78, $11.75*

BASIC PSYCHIATRY FOR CORRECTIONS WORKERS *by* **Henry L. Hartman.** This text will provide a better understanding of the labels attached to mentally ill persons, and will also help the reader feel more comfortable in dealing with such persons. *'78, $16.75*

ALCOHOLISM: The Total Treatment Approach (4th Ptg.) *edited by* **Ronald J. Catanzaro.** This reference guide gives a concise but comprehensive presentation of this complex disease and of the great variety of useful treatment methods and settings available. *'77, $22.50*

MEDICAL AND PSYCHOLOGICAL ASPECTS OF DISABILITY (2nd Ptg.) *by* **A. Beatrix Cobb.** Information relative to diseases of the heart is presented in such a way as to develop a medical vocabulary and to describe the interaction of medical factors with psychosocial components. *'77, $13.75*

THE AMERICAN ALCOHOLIC: The Nature-Nurture Controversy in Alcoholic Research and Therapy (2nd Ptg.) *by* **William Madsen.** Alcoholism and its variations are discussed in relation to biological, psychological and cultural criteria. *'77, $11.50*

THE USE OF ALTERNATIVE MODES FOR COMMUNICATION IN PSYCHOTHERAPY: The Computer, The Book, The Telephone, The Television, The Tape Recorder *by* **David Lester.** Each chapter in this volume is a self-contained review of the literature pertinent to a specific alternative mode of communication and includes a discussion of its unique qualities and its psychotherapeutic ramifications. *'77, $10.50*

RAPE INTERVENTION RESOURCE MANUAL *compiled and edited by* **Patrick Mills.** Possible alternatives to a rape crisis center; legalities involved in establishing the center; how to deal with minors; and material on the selection, training, and evaluation of the staff are only a few of the many topics discussed in this comprehensive resource manual. *'77, $14.75*

HELPING THE MENTALLY RETARDED ACQUIRE PLAY SKILLS: A Behavioral Approach *by* **Paul Wehman.** This book describes how to train leisure time behavior skills in the mentally retarded, including a selection of guidelines for developing play skills in the severely and profoundly retarded. *'77, $12.50*

SCHOOL CONSULTATION: Reading about Preventive Techniques for Pupil Personnel Workers *edited by* **Joel Meyers, Roy Martin** *and* **Irwin Hyman.** Systematically, this volume describes the major approaches to psychoeducational consultation in the schools. *'77, $14.95, paper*

HYPNOSIS AND BEHAVIOR THERAPY *edited by* **Edward Dengrove.** Developed to provide interdisciplinary contact between the schools of behavior therapy and hypnosis, this text covers behavior therapy techniques as well as experiments dealing with the effects of hypnosis upon conditionability and other basic phenomena. *'76, $26.75*

CRISIS SERVICES FOR CAMPUS AND COMMUNITY: A Handbook for the Volunteer *by* **E. Robert Sinnett.** Particular attention is devoted to actual case material in order to identify strategies which will enhance the possibility of lasting success of a volunteer program. *'76, $12.50*

OBESITY: Etiology, Treatment and Management *edited by* **Milton V. Kline, Lester L. Coleman** *and* **Erika E. Wick.** This text deals with the various contributing elements that enter into both the psychological and physiological variables associated with overweight. *'76, $21.75*

THE BIOLOGICAL BASIS OF PERSONALITY (3rd Ptg.) *by* **H. J. Eysenck.** The author proposes a descriptive and causal model of human personality which is consonant with current concepts in experimental psychology. *'77, $18.50*

HYPNOSIS INDUCTION TECHNICS (3rd Ptg.) *by* **Myron Teitelbaum.** Basic methods for inducing hypnosis, determination of the depth of a trance, and awakening the subject are among the topics detailed in this self-teaching text. *'77, $8.50*

THE MALTREATED CHILD: The Maltreatment Syndrome in Children—A Medical, Legal and Social Guide (3rd Ed.) *by* **Vincent J. Fontana** *and* **Douglas J. Besharov.** Among the text's outstanding features are a statistical outline of child abuse, a discussion of medical and social manifestations and preventive measures, and a review of methods of differential diagnosis. *'77, $12.50*

HUMAN NEUROLOGICAL ORGANIZATION (2nd Ptg.) *by* **Edward B. Le Winn.** A readily accessible and collated grouping of basic facts pertaining to the development, clinical characteristics and unique features of human neurological organization is provided. *'77, $10.75*

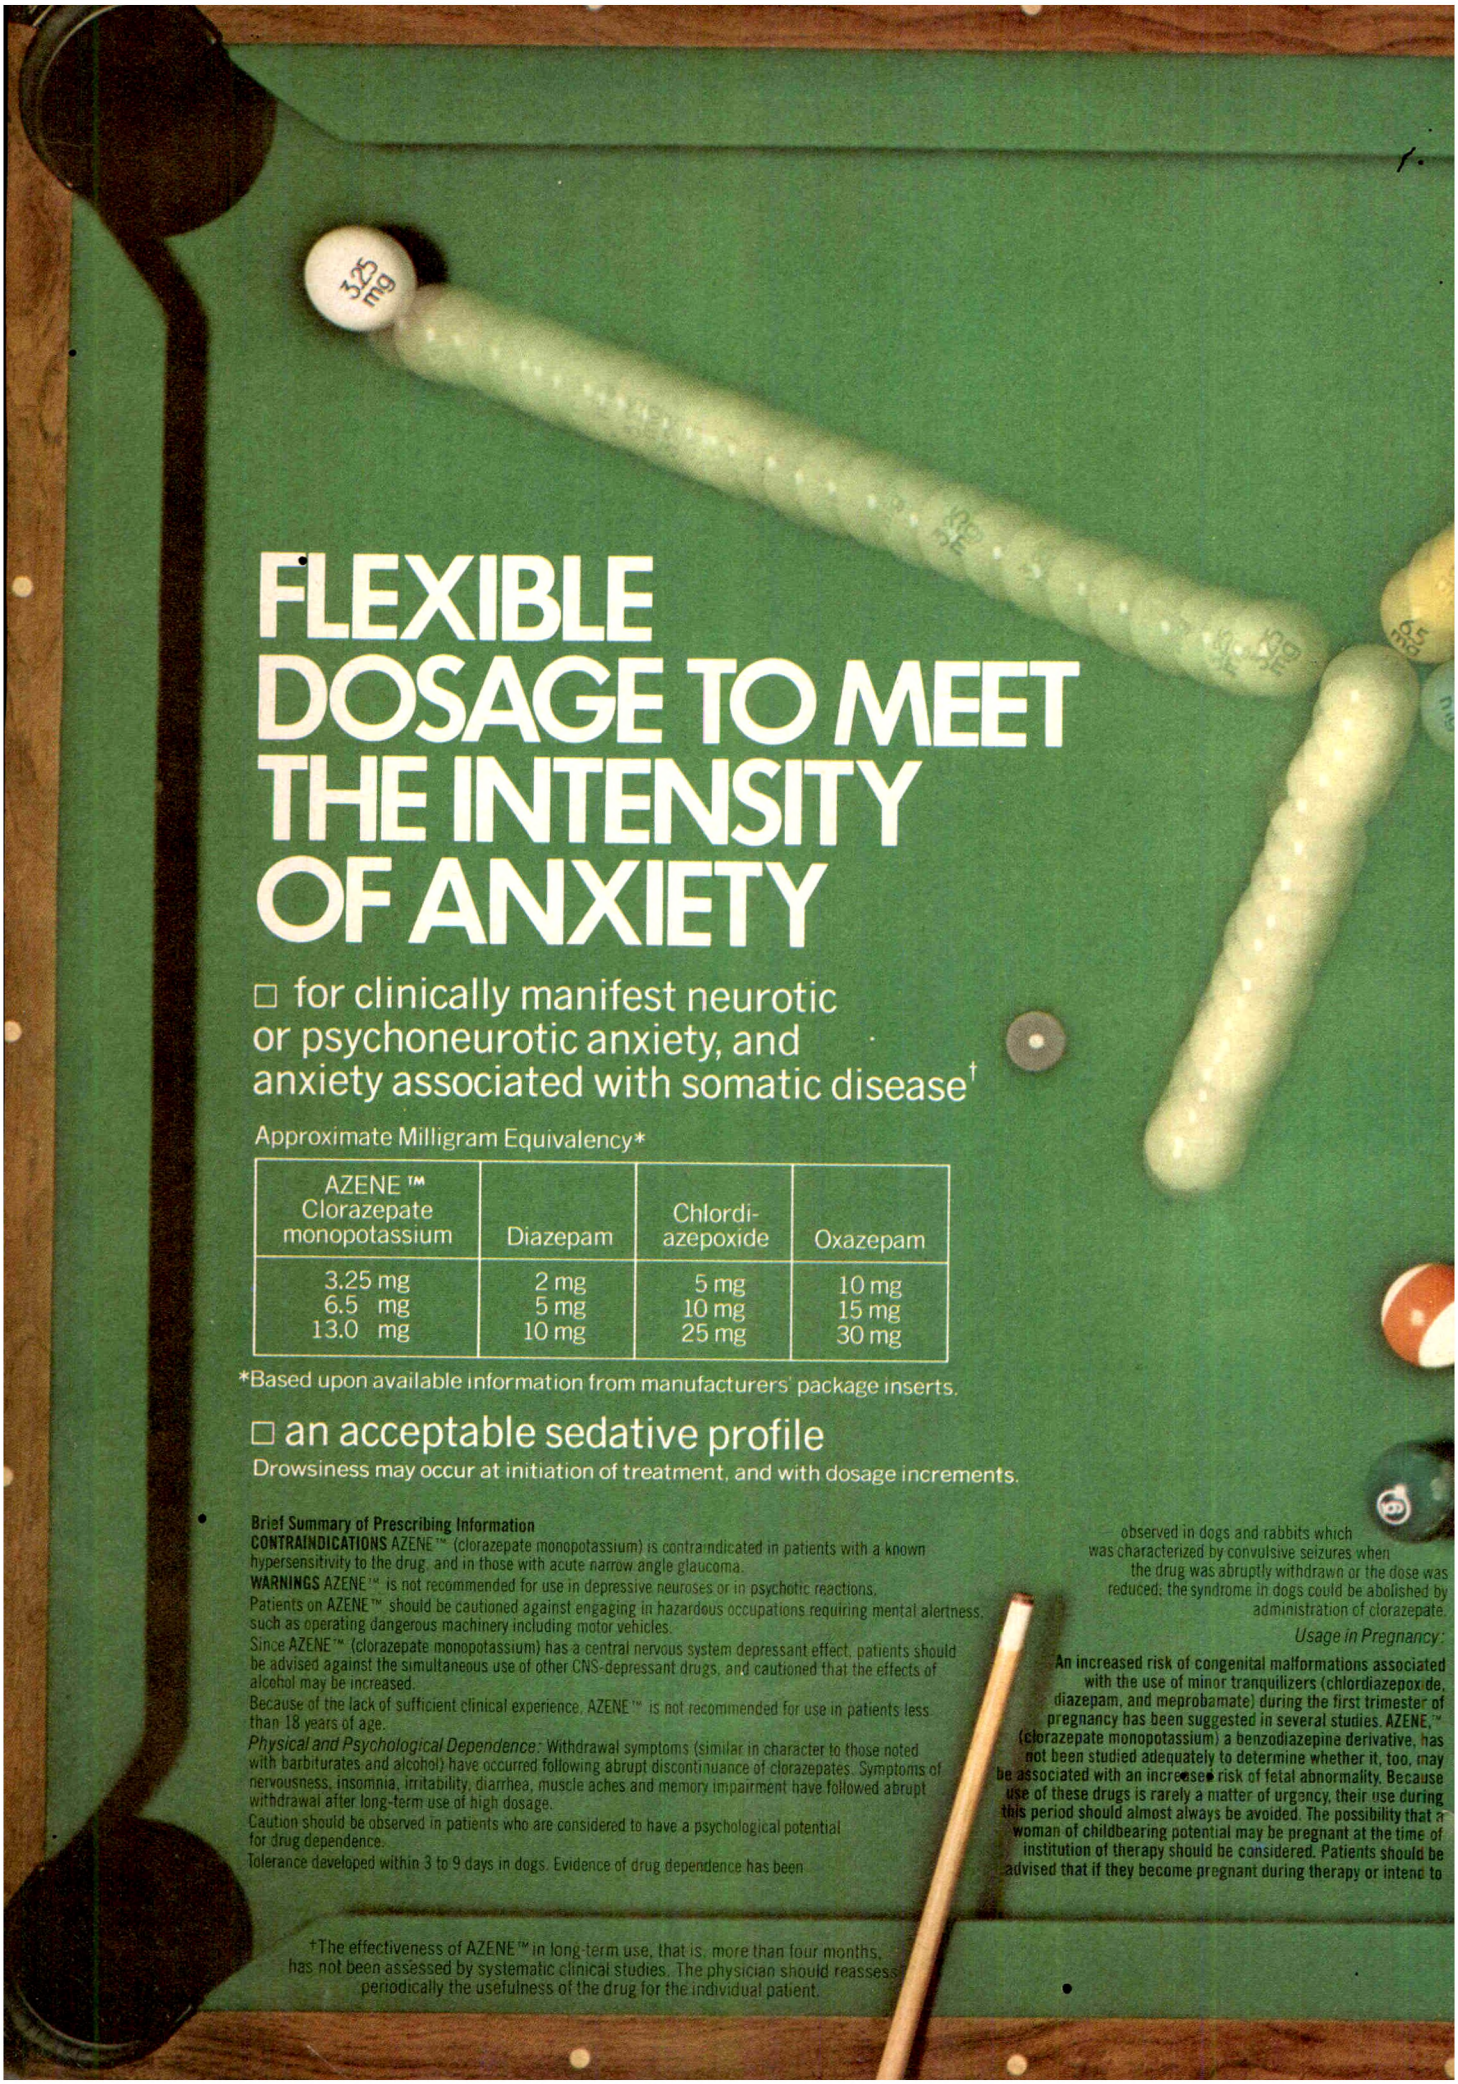
UP FROM UNDERACHIEVEMENT *by* **Gary S. Felton** *and* **Barbara E. Biggs.** The text describes specific techniques for changing maladaptive patterns into success-oriented behaviors, including practical improvement programs related to achievement motivation, communication skills, responsibility, and problem solving. *'77, cloth-$10.50, paper-$6.95*

SENSORY ISOLATION AND PERSONALITY CHANGE *compiled and edited by* **Mark Kammerman.** The effects of sensory deprivation in both bed confinement and water suspension isolation are detailed, as are the uses of sensory isolation as a method of exploring the unconscious mind. *'77, $12.75*

MODERN TECHNIQUES OF VOCAL REHABILITATION (3rd Ptg.) *by* **Morton Cooper.** This book emphasizes simplified, specific techniques to alleviate and/or eliminate all types of functional and organic dysphonias. *'77, $13.95*

THE RETARDED ADULT IN THE COMMUNITY (3rd Ptg.) *by* **Elias Katz.** To meet the needs of retarded adults and their families, the author has devised a comprehensive program in which individuals are prepared to develop normal lives away from the institution. *'77, $12.75*

HOMEWORK IN COUNSELING AND PSYCHOTHERAPY: Examples of Systematic Assignments for Therapeutic Use by Mental Health Professionals (2nd Ptg.) *by* **John L. Shelton** *and* **J. Mark Ackerman.** Examples of effective use of homework assignments for treating sex dysfunction, anxiety reactions, aggression, nonassertive behavior, marital discord, and depression are included. *'76, cloth-$16.75, paper-$12.95*



ACUTE GRIEF AND THE FUNERAL *edited by* **Vanderlyn R. Pine, et al.** The value of the funeral in contemporary society and as a form for the therapeutic expression of grief is underscored through the multidisciplinary approach of this text. *'76, $16.50*

CASE STUDIES OF THE CLINICAL INTERPRETATION OF THE BENDER GESTALT TEST: Illustrations of the Interpretive Process for Graduate Training and Continuing Professional Education *by* **Clifford M. DeCato** *and* **Robert J. Wicks.** Emphasis is placed on illustrating a strategy by which inferences from the Bender Gestalt Test can be derived to arrive at formulations of personality development. *'76, $9.75*

BECOMING A PSYCHOTHERAPIST *by* **Jacquelin Goldman.** Psychotherapy is seen in a general developmental frame of reference, inviting the reader to observe and become involved in many of the major concerns faced in the conduct of psychotherapy. *'76, $9.50*

FLEXIBLE DOSAGE TO MEET THE INTENSITY OF ANXIETY

☐ for clinically manifest neurotic or psychoneurotic anxiety, and anxiety associated with somatic disease†

Approximate Milligram Equivalency*

AZENE ™ Clorazepate monopotassium	Diazepam	Chlordi-azepoxide	Oxazepam
3.25 mg	2 mg	5 mg	10 mg
6.5 mg	5 mg	10 mg	15 mg
13.0 mg	10 mg	25 mg	30 mg

*Based upon available information from manufacturers' package inserts.

☐ an acceptable sedative profile

Drowsiness may occur at initiation of treatment, and with dosage increments.

Brief Summary of Prescribing Information

CONTRAINDICATIONS AZENE™ (clorazepate monopotassium) is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

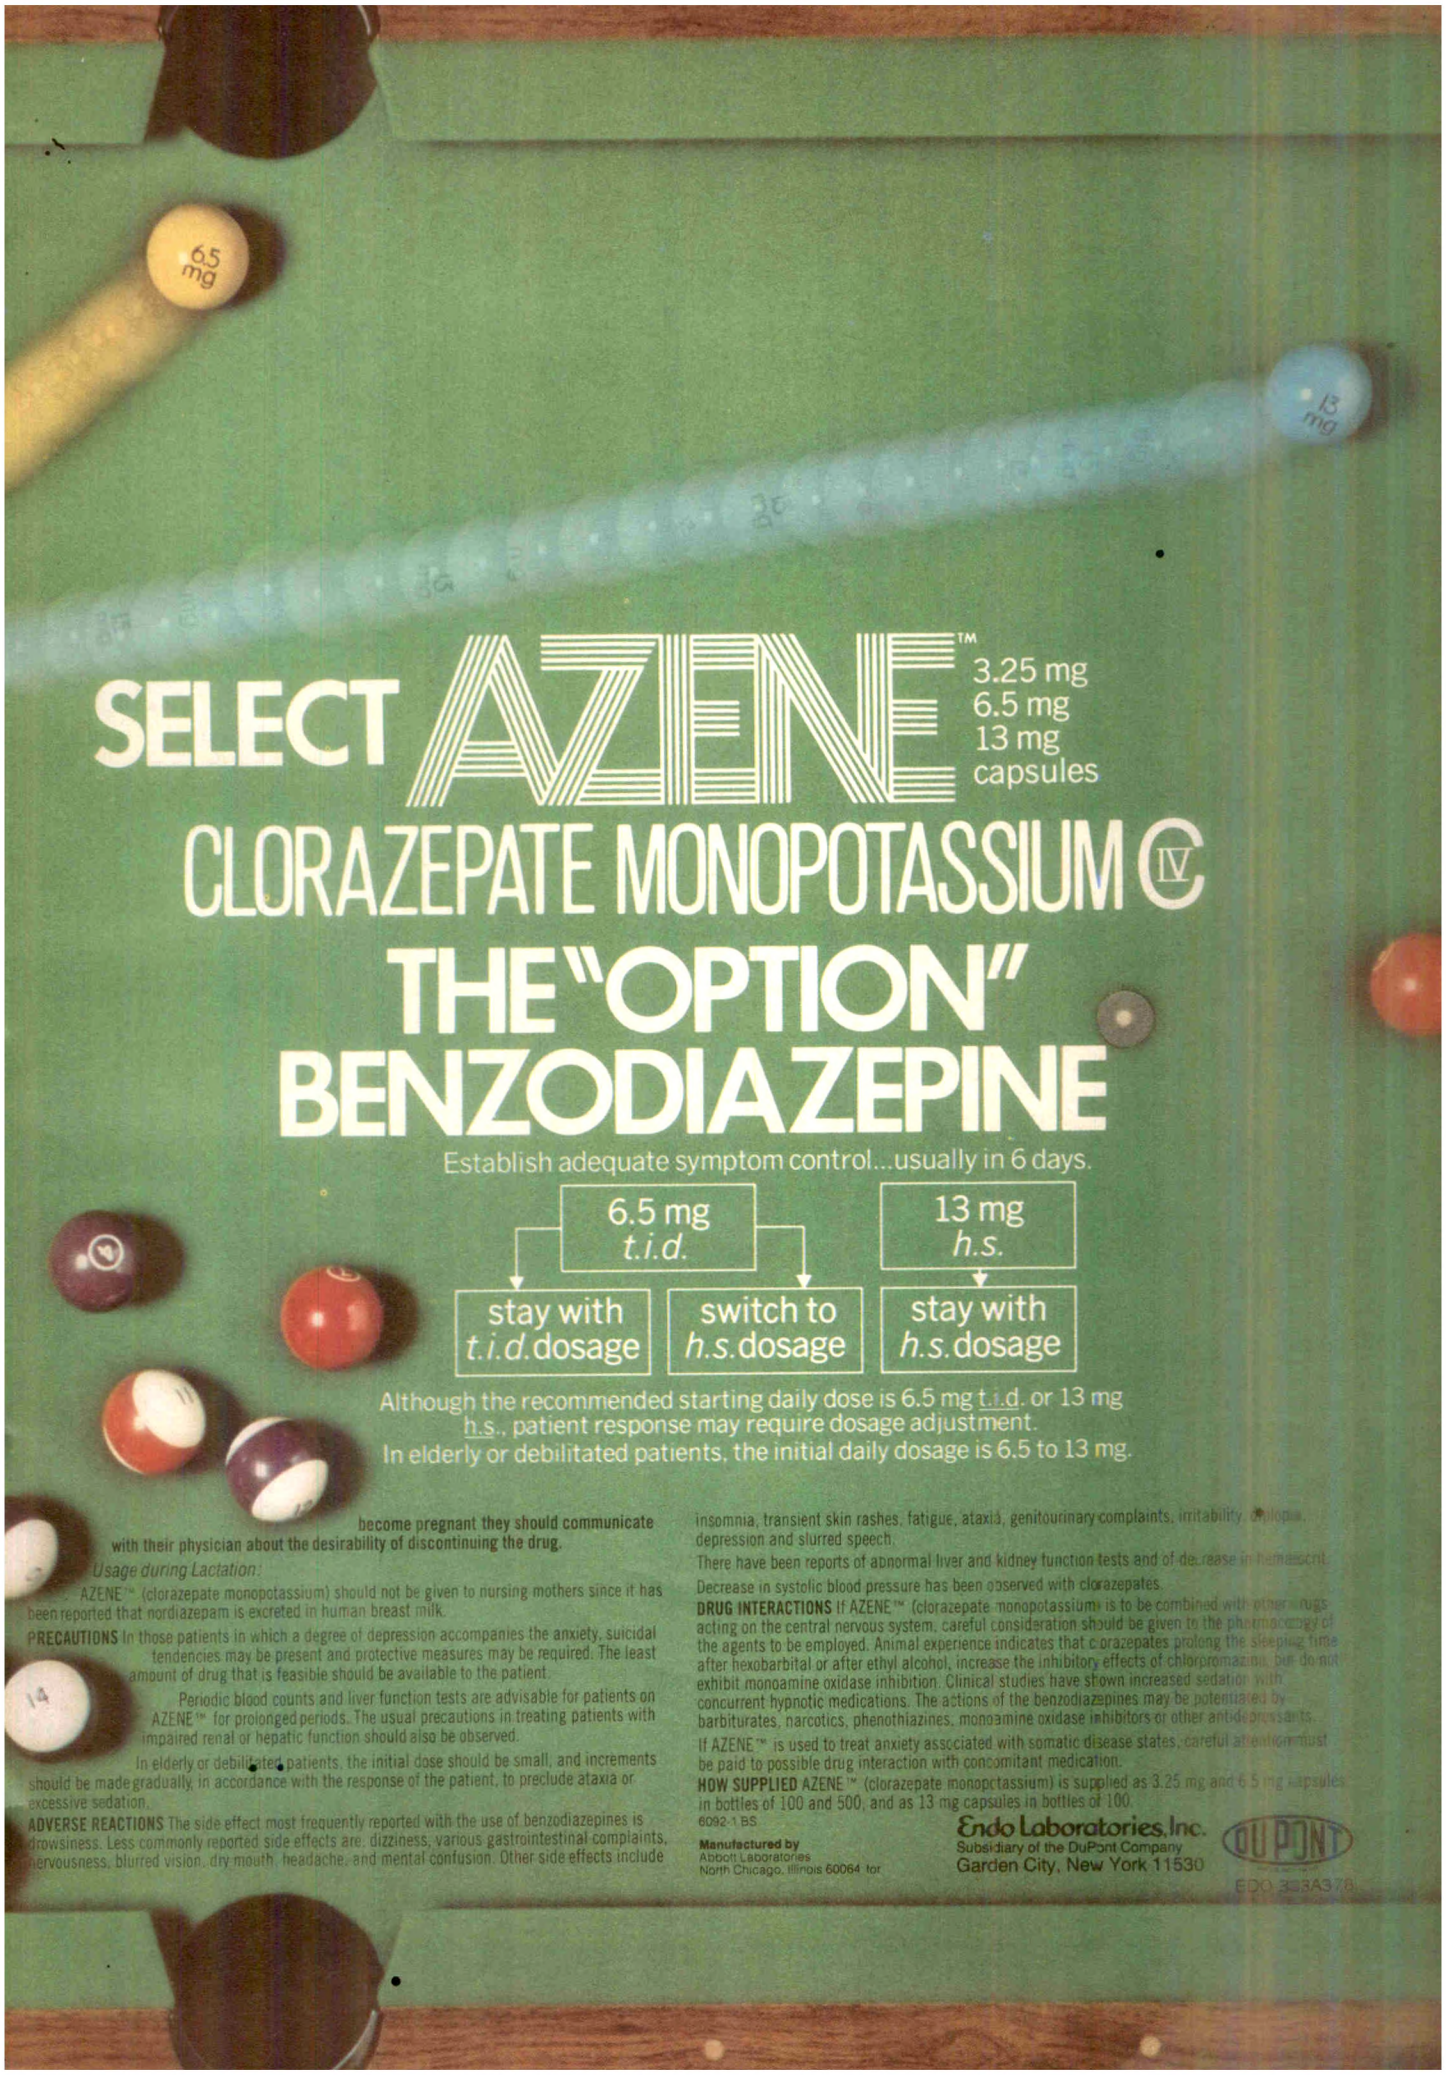
WARNINGS AZENE™ is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on AZENE™ should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since AZENE™ (clorazepate monopotassium) has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, AZENE™ is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepates. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.



Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Tolerance developed within 3 to 9 days in dogs. Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. AZENE,™ (clorazepate monopotassium) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to

†The effectiveness of AZENE™ in long-term use, that is, more than four months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

SELECT AZENE™

3.25 mg
6.5 mg
13 mg
capsules

CLORAZEPATE MONOPOTASSIUM Ⓒ Ⓘⓥ

THE "OPTION" BENZODIAZEPINE

Establish adequate symptom control...usually in 6 days.

6.5 mg *t.i.d.*

- stay with *t.i.d.* dosage
- switch to *h.s.* dosage

13 mg *h.s.*

- stay with *h.s.* dosage

Although the recommended starting daily dose is 6.5 mg t.i.d. or 13 mg h.s., patient response may require dosage adjustment.
In elderly or debilitated patients, the initial daily dosage is 6.5 to 13 mg.

become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

AZENE™ (clorazepate monopotassium) should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Periodic blood counts and liver function tests are advisable for patients on AZENE™ for prolonged periods. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS The side effect most frequently reported with the use of benzodiazepines is drowsiness. Less commonly reported side effects are: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed with clorazepates.

DRUG INTERACTIONS If AZENE™ (clorazepate monopotassium) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that clorazepates prolong the sleeping time after hexobarbital or after ethyl alcohol, increase the inhibitory effects of chlorpromazine, but do not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If AZENE™ is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

HOW SUPPLIED AZENE™ (clorazepate monopotassium) is supplied as 3.25 mg and 6.5 mg capsules in bottles of 100 and 500, and as 13 mg capsules in bottles of 100.

Must the MBD child take a controlled drug in school?

Not if he's taking Cylert® (pemoline) CIV

Children can be cruel. Their teasing about taking noontime medication can cause serious problems for the child with MBD.

Here's how Cylert eliminates this problem:

- Once a day dosage at home
- Eliminates mid-day school dose

In addition, Cylert offers these benefits:

- Avoids ups and downs of drug action brought about by multiple daily dosage
- Control of medication by the parent
- A chewable dosage form
- Less physician paper work (Cylert is in schedule IV)
- Safety and efficacy proven in extensive clinical studies*

*Copy of the Cylert Monograph available to Physicians on written request.

UNIVERSITY COLLEGE OF MEDICINE LIBRARY

When not to use medication

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school-age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

8083261

ABBOTT

Please see next page for Prescribing Information.

Cylert and Cylert Chewable Tablets

(pemoline)

Prescribing Information

Indications: *MINIMAL BRAIN DYSFUNCTION IN CHILDREN*—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations: The cause of minimal brain dysfunction (MBD) is unknown. Diagnosis of MBD involves the use of medical, psychological, educational, and social tools, since no single diagnostic test is adequate.

MBD is characterized by chronic moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindications: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See ADVERSE REACTIONS.)

Warnings: Cylert is not recommended for children less than 6 years of age since its safety and efficacy in this age group have not been established.

Sufficient data on the safety and the efficacy of the long-term use of Cylert in children with minimal brain dysfunction are not yet available.

A temporary suppression of the predicted growth rate (weight and/or height gain) has been reported for children receiving long-term stimulant therapy. A definite causal relationship between stimulant drugs and this finding has not been established.

Precautions: Liver function tests should be performed periodically during therapy with Cylert. The drug should be discontinued if abnormalities are revealed and confirmed by follow-up tests. (See ADVERSE REACTIONS regarding reports of abnormal liver function tests and jaundice.)

Cylert should be administered with caution to patients with significantly impaired hepatic or renal function.

The interaction of Cylert with other drugs has not been studied in humans. Patients who are receiving Cylert concurrently with other drugs, especially drugs with CNS activity, should be monitored carefully.

Cylert failed to demonstrate a potential for self-administration in primates. However, the pharmacologic similarity of pemoline to other psychostimulants with known dependence liability suggests that psychological and/or physical dependence might also occur with Cylert. There have been isolated reports of transient psychotic symptoms occurring in adults following the long-term misuse of excessive oral doses of pemoline. Cylert should be given with caution to emotionally unstable patients who may increase the dosage on their own initiative.

Usage during Pregnancy and Lactation: The safety of Cylert (pemoline) for use during pregnancy and lactation has not been established.

Fertility, reproduction, and teratology studies were conducted in laboratory animals. Pemoline, in doses of 18.75 or 37.5 mg./kg./day, had no effect on the fertility of male or female rats. The drug, when given to pregnant rats (from gestation day 15 through weaning) and to rabbits (from gestation days 6-18) at these same dosage levels, produced no teratogenic or embryotoxic effects, and had no effect on the viability of the young at birth. However, increased incidences of stillbirths and cannibalization were observed when pemoline was given to rats at these dosage levels, beginning 14 days prior to conception.

Adverse Reactions: Insomnia is the most frequently reported side effect of Cylert; it usually occurs early in therapy, prior to an optimum therapeutic response. In the majority of cases it is transient in nature or responds to a reduction in dosage.

Anorexia with weight loss may occur during the first weeks of therapy. In the majority of cases it is transient in nature; weight gain usually resumes within three to six months.

Stomach ache, skin rashes, increased irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations have been reported.

Elevations of SGOT, SGPT, and serum LDH have occurred in patients taking Cylert, usually after several months of therapy. These effects appear to be reversible upon withdrawal of the drug, and are thought to be manifestations of a delayed hypersensitivity reaction. There have also been a few reports of jaundice occurring in patients taking Cylert; a causal relationship between the drug and this clinical finding has not been established.

There have been reports of dyskinetic movements of the lips, face, and extremities occurring with the use of Cylert. Convulsive seizures have also been reported. A definite causal relationship between Cylert and these reactions has not been established.

Mild adverse reactions appearing early during the course of treatment with Cylert often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage should be reduced or the drug discontinued.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (white) in bottles of 100 (**NDC** 0074-6025-13)
37.5 mg. tablets (orange-colored) in bottles of 100 (**NDC** 0074-6057-13)
75 mg. tablets (tan-colored) in bottles of 100 (**NDC** 0074-6073-13)

Cylert Chewable is supplied as monogrammed, grooved tablets in one dosage strength:

37.5 mg. tablets (orange-colored)
in bottles of 100 (**NDC** 0074-6088-13)

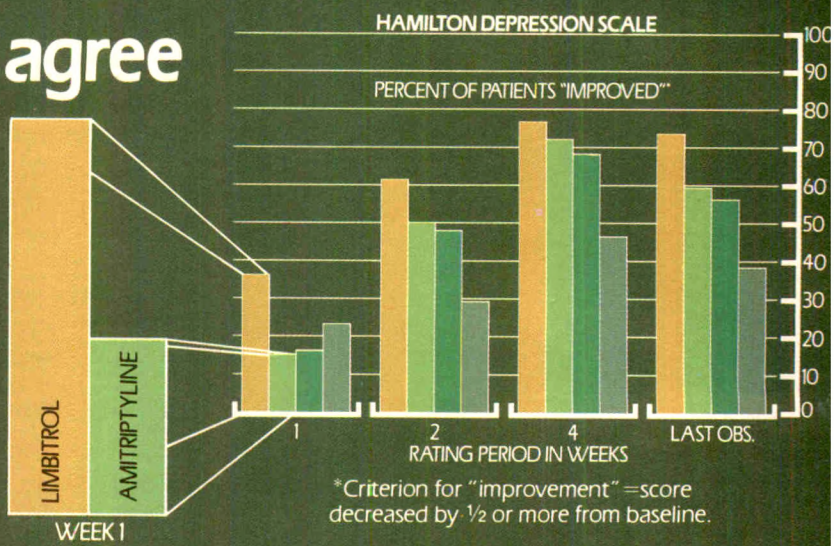
Within one week
A better response
For twice as many patients

compared to amitriptyline alone

Limbitrol®

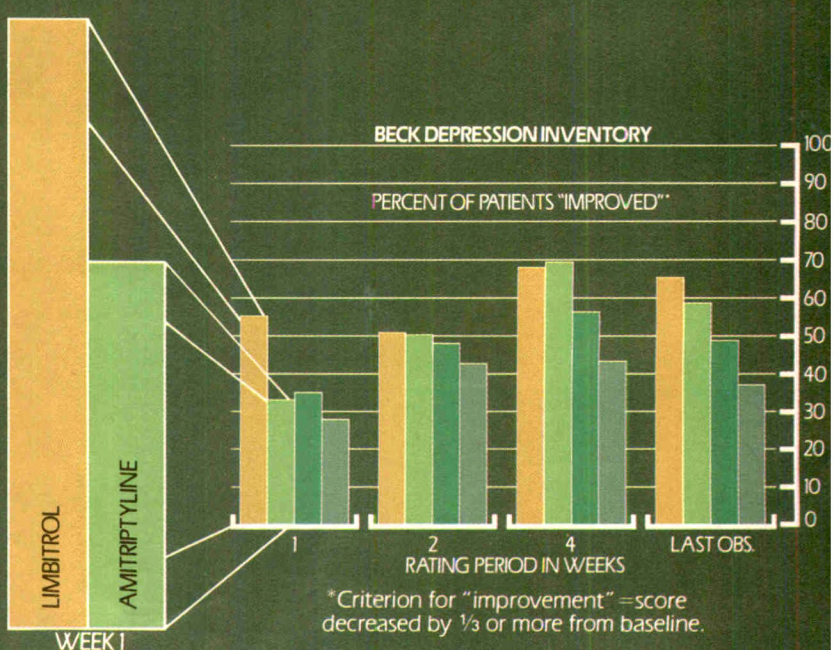
For rapid relief of symptoms in moderate to severe depression and anxiety

ROCHE



Please see last page of this advertisement for summary of product information.

Within one week
Twice as many patients improved–sooner

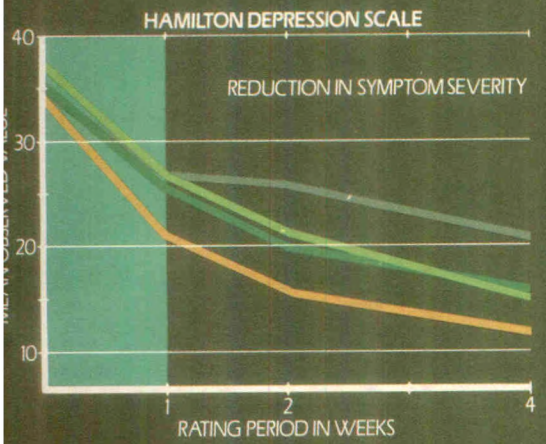


In a rigidly controlled
nationwide multicenter study

The rating scales agree

- ☐ Patients respond faster
  - ☐ Limbitrol—in the first week approximately 2/3 of those who improved had already done so
  - ☐ Amitriptyline—only about 1/3 of those who eventually responded had done so by week one
- ☐ High correlation among all major indices employed including Physician's and Patient's Global Evaluations

*Criterion for "improvement" =score decreased by ½ or more from baseline.



*Criterion for "improvement" =score decreased by ⅓ or more from baseline.

How to initiate and maintain therapy

Select dosage strength appropriate for each patient

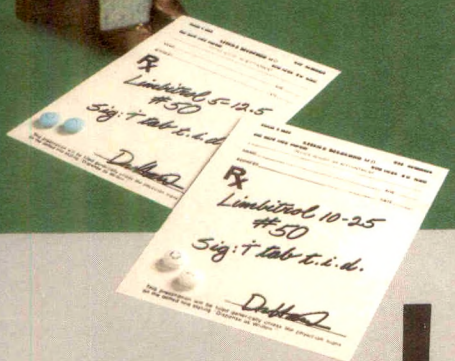
☐ Limbitrol 10-25 is recommended for most patients

☐ Limbitrol 5-12.5 may be indicated for those who do not tolerate higher doses and for elderly patients

Specify daily dosage based on symptom severity

☐ An initial dosage of three tablets is recommended

☐ Dosage may be increased to six tablets or decreased to two tablets daily as necessary



☐ Once a satisfactory response is obtained, evaluate response, and, if necessary, reduce dosage to smallest amount needed to maintain remission

Utilize dosage options to best accommodate individual patient needs

☐ T.I.D. or Q.I.D., familiar regimens most suited for patients who tolerate medication without undue drowsiness

☐ Two tablets one hour before bedtime and one tablet midday may minimize daytime drowsiness and help relieve a common target symptom—insomnia

☐ Entire dosage *h.s.* to take maximum advantage of the sedative effect

Tablets 10-25 each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt)

Tablets 5-12.5 each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)

Limbitrol®

For rapid relief of moderate to severe depression and anxiety

Your guide to patient management

1. Discuss with patients the probability that they will experience drowsiness, especially during the first week.
2. Reassure your patients that drowsiness is one indication that the medication is working and that it may help alleviate their insomnia.
3. Encourage patients to report if drowsiness becomes troublesome so that, if necessary, dosage schedule can be adjusted or the symptom treated.
4. Caution patients about the combined effects with alcohol or other CNS depressants. Let them know that the additive effects may produce a harmful level of sedation and CNS depression.
5. Caution patients about activities requiring complete mental alertness, such as operating machinery or driving a car.
6. Warn pregnant patients and patients of childbearing age that the safety of Limbitrol in pregnancy has not yet been established.

Please see complete product disclosure for other pertinent information

Limbitrol should not be used under the following circumstances:

1. Hypersensitivity to benzodiazepines or tricyclic antidepressants.
2. Should not be given with an MAO inhibitor. To replace an MAO inhibitor with Limbitrol, discontinue MAO inhibitor for a minimum of 14 days before cautiously initiating Limbitrol therapy.
3. During the acute recovery phase following myocardial infarction.

Limbitrol®

For rapid relief of moderate depression and anxiety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of symptoms of depressive disorders associated with moderate to severe anxiety.

Contraindications: Known hypersensitivity to benzodiazepines or tricyclic antidepressants. Do not use with monoamine oxidase (MAO) inhibitors or within 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use. When initiate cautiously, gradually increasing dosage until optimal response is achieved. Contraindicated during acute recovery phase following myocardial infarction.

Warnings: Use with great care in patients with history of urinary retention or angle-closure glaucoma. Severe constipation may occur in patients taking tricyclic antidepressants and anticholinergic-type drugs. Closely supervise cardiovascular patients (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, especially high doses. Myocardial infarction and stroke reported with use of this class of drugs.)

Usage in Pregnancy: **Use of minor tranquilizers during the first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Since physical and psychological dependence to chlordiazepoxide have been reported rarely, use caution in administering Limbitrol to addiction-prone individuals or those who might increase dosage. Withdrawal symptoms following discontinuation of either component alone have been reported (nausea, headache and malaise for amitriptyline; symptoms [including convulsions] similar to those of barbiturate withdrawal for chlordiazepoxide).

Precautions: Use with caution in patients with a history of seizures, in hyperthyroid patients or those on thyroid medication and in patients with impaired renal or hepatic function. Because of the possibility of suicide in depressed patients, do not permit easy access to large quantities in these patients. Caution patients about possible combined effects with alcohol and other CNS depressants and against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Periodic liver function tests and blood counts are recommended during prolonged treatment. Amitriptyline component may block action of guanethidine or similar antihypertensives. Concomitant use with other psychotropic drugs has not been evaluated; sedative effects may be additive. Discontinue several days before surgery. Limit concomitant administration of ECT to essential treatment. See Warnings for precautions about pregnancy. Limbitrol should not be taken during the nursing period. Not recommended in children under 12. In the elderly and debilitated, limit to smallest effective dosage to preclude ataxia, overreaction, confusion or anticholinergic effects.

Adverse Reactions: Most frequently reported are those associated with other components alone: drowsiness, dry mouth, constipation, blurred vision, dizziness and bloating. Less frequently occurring reactions include vivid dreams, impotence, tremor, confusion and nasal congestion. Many depressive symptoms including anorexia, fatigue, weakness, restlessness and lethargy have been reported as side effects of both Limbitrol and amitriptyline. Granulocytopenia, jaundice and hepatic dysfunction have been observed rarely.

This list includes adverse reactions not reported with Limbitrol but requiring consideration because they have been reported with one or both components or closely related drugs.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Euphoria, apprehension, poor concentration, delusions, hallucinations, hypomania and increased or decreased libido.

Neurologic: Incoordination, ataxia, numbness, tingling and paresthesias of the extremities, extrapyramidal symptoms, syncope, changes in EEG patterns.

Anticholinergics: Disturbance of accommodation, paralytic ileus, urinary retention, dilatation of urinary tract.

Allergic: Skin rash, urticaria, photosensitization, edema of face and tongue, pruritus.

Hematologic: Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue.

Endocrine: Testicular swelling and gynecomastia in the male; breast enlargement, galactorrhea and minor menstrual irregularities in the female and elevation and lowering of blood sugar levels.

Other: Headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, jaundice, alopecia, parotid swelling.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. I.V. administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestation and treatment.

Dosage: Individualize according to symptom severity and patient response. Reduce to smallest effective dosage when satisfactory response is obtained. Larger portion of daily dose may be taken at bedtime. Single-dose may suffice for some patients. Lower dosages are recommended for the elderly.

Limbitrol 10-25, initial dosage of three to four tablets daily in divided doses, increased up to six tablets or decreased to two tablets daily as required. Limbitrol 5-12.5, initial dosage of three to four tablets daily in divided doses for patients who do not tolerate higher doses.

Supplied: Limbitrol 10-25 tablets each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt) and Limbitrol 5-12.5 tablets each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt) – bottles of 100 and 500, Tel-E-Dose® packages of 100, Prescription Paks of 50.

The overlooked pioneer.

Karen Horney's theories—particularly in feminine psychology and the role of social and cultural forces in personality formation—have become so widely accepted that her role in formulating them is often overlooked. But at the height of her career, her repeated challenges to Freudian orthodoxy made her a center of controversy on both sides of the Atlantic. Jack Rubins' biography—the first full-length study of Horney's life and work—captures all the drama of that era, showing how her thinking developed and why her boldness and originality place her among the most important pioneers of psychoanalysis. Illustrated with photographs, $9.95

FORENSIC PSYCHIATRY CLINIC OF THE NEW YORK STATE CRIMINAL AND SUPREME COURTS OF MANHATTAN
offer

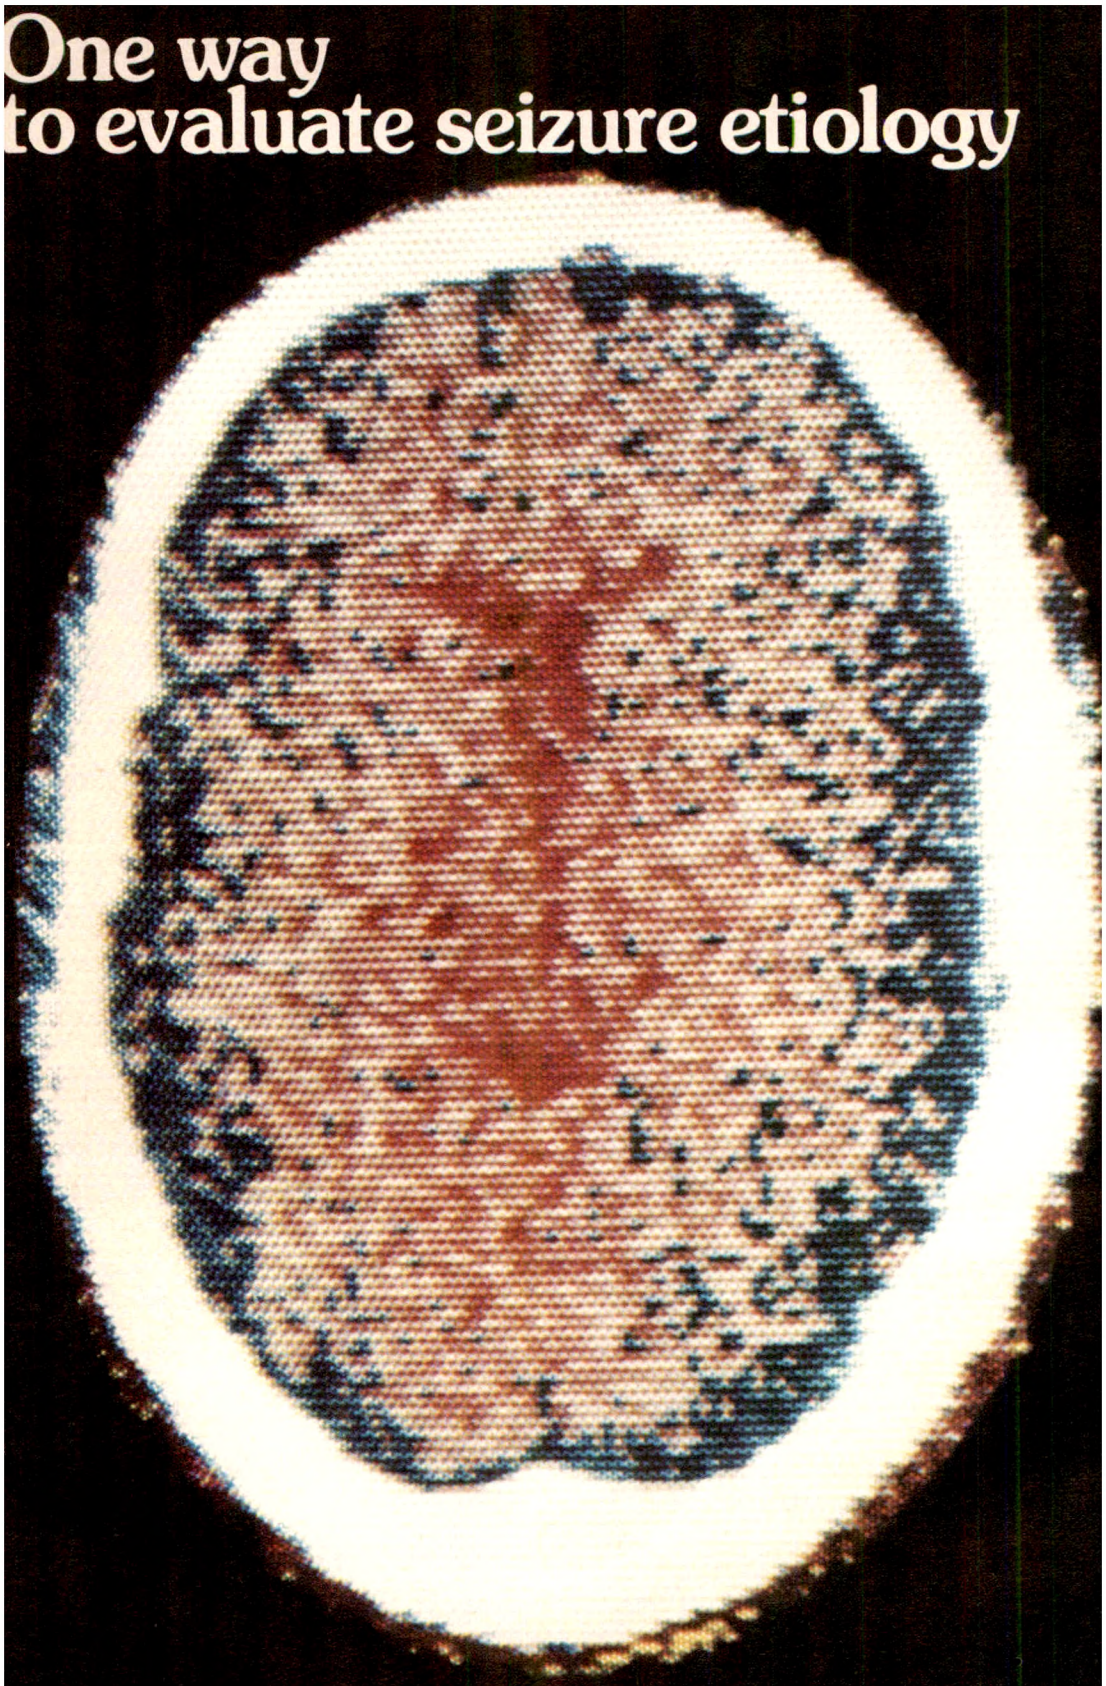
A PRACTICUM IN PSYCHIATRY AND THE CRIMINAL LAW

Saturday and Sunday **December 2 and 3, 1978**

Course Director: Richard Rosner, M.D.

This course assists psychiatrists to understand better their role at the interface of psychiatry and the criminal law. It is built on the premise that special training is essential if psychiatrists are to function effectively in the legal arena and that such training can be provided in the context of an intensive lecture-discussion series. The aim is to produce practitioners of forensic psychiatry rather than physicians who have merely an intellectual grasp of the field.

The program emphasizes practical clinical issues such as essential philosophical and procedural differences between psychiatry and the law, the preparation of psychiatric reports for legal purposes, competency to stand trial, insanity as a defense against criminal responsibility, pre-sentence consultation to guide judicial decisions, how to effectively confer with attorneys prior to court hearings, involuntary hospitalization, the right to treatment and the right to refuse treatment.



Sessions include lectures, seminar discussions and ample opportunity for questions and informal interchange with the faculty.

Accreditation: 14 hours AMA Category I

Tuition: $160

One way to evaluate seizure etiology

Computerized transaxial tomography (CT scan) is an important new noninvasive techniqu
that can help in determining the etiology of epileptic seizures. Shown here is a single slice
from a color-enhanced CT scan of the brain of a patient with epilepsy. The absence of vasc

A proven way to start seizure control

MYSOLINE®
(primidone)

Tablets 50 mg, 250 mg
Suspension 250 mg/5 ml

A single entity with multiple anticonvulsant properties

Primidone itself has anticonvulsant activity. In addition, its major metabolite, phenylethylmalonamide (PEMA), exerts an anticonvulsant effect of its own and also enhances the anticonvulsant action of the second metabolite, phenobarbital. In patients refractory to phenytoin and phenobarbital, primidone may prove effective as the sole therapy.[1]

Multiple indications—grand mal, psychomotor, and focal epileptic seizures

In grand mal, MYSOLINE is comparable in efficacy to phenytoin and phenobarbital.[2,3] In psychomotor seizures, phenobarbital is rarely effective.[1] In focal seizures, phenytoin used alone is not indicated[4]—and, according to Forster,[3] MYSOLINE is markedly more effective than phenobarbital, which should dispel the misconception that MYSOLINE is "just a phenobarbital." (See chart below.)

Efficacy ratings* of anticonvulsants in epilepsy

Agent	Grand Mal	Psychomotor	Focal
Mysoline	++++	++++	++++
Hydantoinates (phenytoin)	++++	+++	+++
Barbiturates (phenobarbital)	++	++	++

*Relative effectiveness, ++++ being most effective. Adapted from Forster, F. M.[3]

Consider it first for major motor epilepsies

MYSOLINE® (primidone) Ayerst®

See next page for Brief Summary and references.

Start seizure control with MYSOLINE® (primidone)

Initial dose in children over 8 years of age and adults: 250 mg daily at bedtime

BRIEF SUMMARY
(For full prescribing information, see package circular.)
MYSOLINE®
Brand of **PRIMIDONE** *Anticonvulsant*

ACTIONS: MYSOLINE raises electro- or chemoshock seizure thresholds or alters seizure patterns in experimental animals. The mechanism(s) of primidone's antiepileptic action is not known.

Primidone *per se* has anticonvulsant activity as do its two metabolites, phenobarbital and phenylethylmalonamide (PEMA). In addition to its anticonvulsant activity, PEMA potentiates that of phenobarbital in experimental animals.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several weeks before it can be assessed.

Usage in pregnancy: The effects of MYSOLINE in human pregnancy and nursing infants are unknown.

Recent reports suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Data are more extensive with respect to diphenylhydantoin and phenobarbital, but these are also the most commonly prescribed anticonvulsants; less systematic or anecdotal reports suggest a possible similar association with the use of all known anticonvulsant drugs.

The reports suggesting an elevated incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodologic problems in obtaining adequate data on drug teratogenicity in humans; the possibility also exists that other factors, *e.g.*, genetic factors or the epileptic condition itself, may be more important than drug therapy in leading to birth defects. The great majority of mothers on anticonvulsant medication deliver normal infants. It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

PRECAUTIONS: The total daily dosage should not exceed 2 g. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 g per day. The initial dose is 250 mg. Increments of 250 mg are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 g. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg daily at bedtime	*2nd Week* 250 mg b.i.d.
3rd Week 250 mg t.i.d.	*4th Week* 250 mg q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg, with gradual weekly increases of 125 mg a day, to a daily total usually between 500 mg and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE Tablets—No. 430—Each tablet contains 250 mg of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg of primidone (scored), in bottles of 100 and 500.
MYSOLINE Suspension—No. 3850—Each 5 ml (teaspoonful) contains 250 mg of primidone, in bottles of 8 fluidounces.

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

Artist Leonard Leff uses sculpture to express the painful depression he once experienced. He remembers it as "a lowering of the flame of life. My energies ebbed, my will to live decreased, and I found myself retreating from the activities of life to a more introverted existence."

WHEN DEPRESSION EXPRESSES ITSELF

SINEQUAN®
(DOXEPIN HCl)

ANTIDEPRESSANT EFFECTIVENESS with convenient once-a-day *h.s.* dosage*

NEW 150-MG CAPSULE†

Also available in:
100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

† The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)
NEW 150-MG CAPSULE*

*The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting daily dose of 75 mg is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-day dosage schedule. If the once-a-day schedule is employed the maximum recommended dose is 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.**

Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus), hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days, since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 75 mg, and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg and 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 mg doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not with grape juice. Preparation and storage of bulk dilutions is not recommended.

More detailed professional information available on request.

Patients become easier to manage

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent
- not a phenothiazine

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information.

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

For complete prescribing information, please see next page.

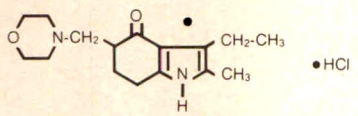
DUPONT

Patients become easier to manage on



MOBAN®

molindone HCl

5 mg	10 mg	25 mg
Endo	Endo	Endo

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose—
20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose—
20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose—
5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN® Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencies and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

The Joint Information Service of the American Psychiatric Association and the Mental Health Association releases Two New Volumes That

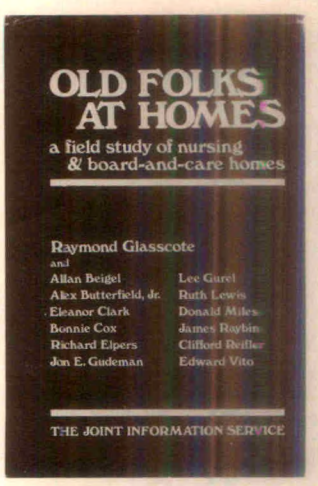
Focus on the Elderly

This carefully documented book reports a field study of ten programs, four in America and six in England and Scandinavia, which serve as practical demonstrations of creative mental health services for the elderly. They include:

- a novel "Neighborhood Family" providing vigorous support to elderly residents of several trailer parks
- a high school for the elderly which sends its students abroad for study trips
- a "Human Development Project" that focuses on responding to the psychological needs of the elderly
- a carefully coordinated system of "respite hospitalization," which promotes the health of the elderly while allowing maximum use of hospital beds and family resources
- a "Lucy Booth," patterned after the Peanuts comic strip, which provides easy access to many kinds of services
- and many other innovative, successful approaches.

Each program is subjected to intensive scrutiny. The resulting document becomes a handbook, and, as well, a forum through which some of the world's most experienced practitioners of "the psychiatry of old age" present their views.

Dr. Wilma Donohue, director of the International Center for Social Gerontology, characterizes this volume as "a masterful job of putting everything in relief . . . the guidelines for action are right here."



190 pages. Casebound. Price $8.50.

Concerned about the very bad reputation that nursing homes have received from many quarters in recent years, the Joint Information Service set up a field study to visit a systematically chosen sample of nursing homes, and board-and-care homes as well, to see to what extent the care of and the quality of life for the patients differed from the geriatrics units of state hospitals. Altogether, sixty nursing homes and 31 board-and-care homes in ten locales were visited, in each case by the senior author accompanied by two mental health professionals.

The teams were surpised to learn that care and quality of life in many of the nursing and board-and-care homes they visited were better—sometimes dramatically better—than that in the mental health facilities and often at lower cost.

This unique publication provides an overview of all facilities visited plus vignettes of approximately half. Federal and state rules and regulations are also expertly synthesized into brief and readable style.

148 pages. Casebound. Price $6.50

"Please don't cry."

His mother's depressed. Her sleepless nights are filled with anxieties. She's become irritable and "unloving." He doesn't understand why she has changed.

In anxious depressed patients, Goldberg and Finnerty* found "...patients treated with imipramine pamoate tended ($P<.09$) to have a better quality of sleep than those treated with amitriptyline."

The overall results of the study indicate that both imipramine pamoate and amitriptyline were equally effective in treating neurotic depression.

Before prescribing Tofranil-PM, please review a summary of the full prescribing information on the following page.

Tofranil-PM®
imipramine pamoate

Unsurpassed among tricyclics in treating symptoms of anxious depression

*Goldberg H L, Finnerty R J: Which tricyclic for depressed outpatients, imipramine pamoate or amitriptyline? Dis Nerv Syst 38: 785-789 (Oct.) 1977.

Geigy

Tofranil-PM®
imipramine **pamoate**

Geigy

As anxiety, agitation, sleep disturbances, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

ANXIETY

SURVEY OF 2244 ADULTS SHOWS A CHANGING PICTURE OF PERSONS AT HIGH RISK...

The results of an ongoing Chicago area survey[1] reveal that, contrary to patterns of the past, *day-to-day social stressors such as marriage, parenting and the job account for three to four times more symptoms of anxiety than do demographic factors or early emotional traumas.*

Persons with high symptomatology were defined as the top 13% of the sample. The situations and stresses these people face in their lives are the variables that place them at high risk for anxiety.

The Separated-from-Spouse Person

Persons separated from their spouses showed the highest incidence—40%—of high anxiety symptoms of any group in the survey. Married persons are at lowest risk for any group, with single, widowed and divorced people slightly higher.

The Lowest-Income, Least-Skilled Person

When examined according to socioeconomic variables, the data reveal that persons with the lowest income and occupational status show twice as much symptomatology as the four socioeconomic levels above them, in whom symptomatology varied little. Moreover, high risk demographic variables tend to cluster: considered independently, women and single people show high symptomatology, and 75% of the respondents in the lowest income level were female and 82% were unmarried.

Prevalence of anxiety symptoms by income, education, and occupational status[1]

	HIGH	OTHER	NUMBER OF RESPONDENT
Entire Sample	13%	87%	2,244
*INCOME LEVEL			
highest—1	13%	87%	77
2	7%	93%	267
3	9%	91%	845
4	13%	87%	544
lowest—5	32%	68%	220
*EDUCATIONAL LEVEL

ROCHE

The Person with 3 or more Concurrent Social Stressors

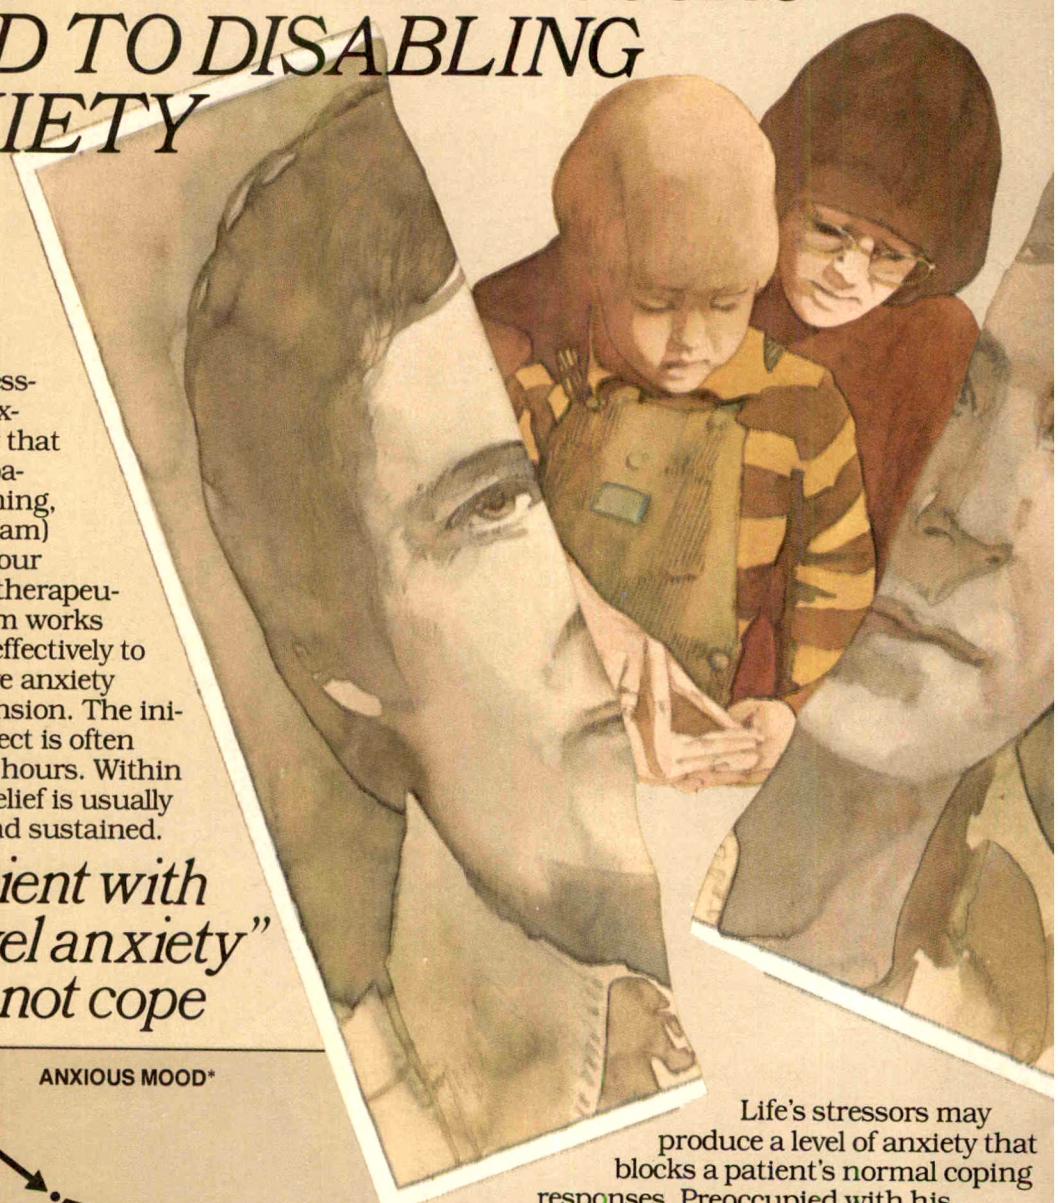
When subjects are divided into groups based on the number of their current social stressors, it is clear that the percentage of subjects with high symptomatology increases sharply with increasing numbers of stressors. Only 3% of subjects with no current social stressors report high symptoms of anxiety; of those with three or more current stressors, 28% reported high symptoms ($p<.001$).

The Marital Stressor:

Marital/singlehood stressors had the highest and most significant correlation with symptoms of anxiety for all groups except employed single women. For single men and women, differing profiles emerge: the relationship between these stressors and anxiety is much closer for men than for women.

The Job Stressor:

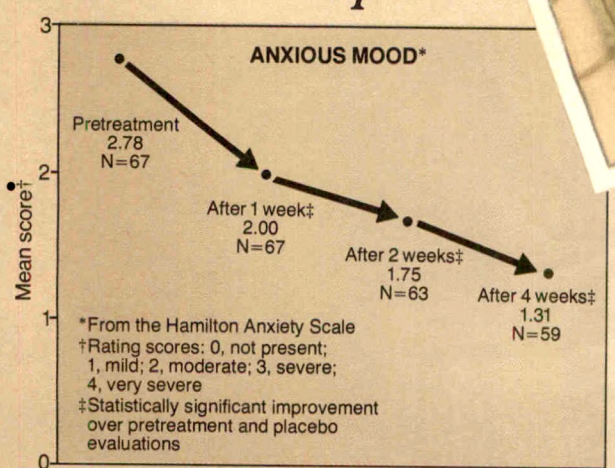
Current stressors related to the job are, after marital stressors, the most closely related to anxiety symptoms for employed married fathers, and are also high for single men. For women, married or single, there was no correlation between job and anxiety. The only significant correlation with anxiety for employed single women was financial stressors.



The Parental Stressor:

The interaction of current social stressors with demographic factors can be seen when the parental stressor is examined. This variable is positively correlated with anxiety in all mothers, but to a much more significant degree in unemployed mothers. Parental stressors are also related to anxiety in fathers, but at a lower correlation and with less significance than in employed or unemployed mothers.

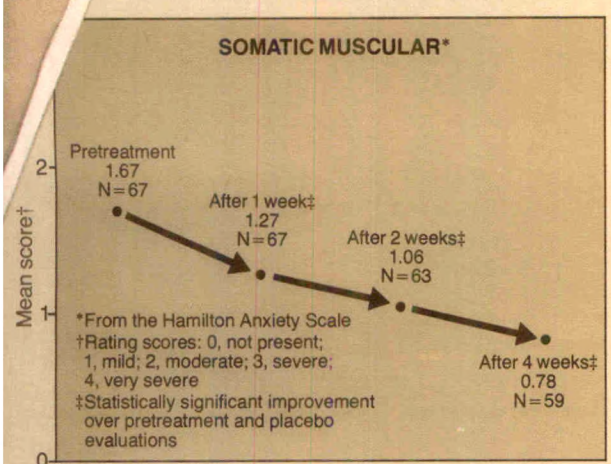
1. Ilfeld FW, Jr: Persons at high risk for symptoms of anxiety. Presented at Excerpta Medica symposium "Clinical Anxiety/Tension in Primary Medicine," Washington, D.C., September 1977



WHEN LIFE'S STRESSORS LEAD TO DISABLING ANXIETY

When the level of stress or the number of stressors produces excessive anxiety that inhibits your patient's functioning, Valium (diazepam) can be one of your most valuable therapeutic allies. Valium works promptly and effectively to relieve excessive anxiety and psychic tension. The initial calming effect is often evident within hours. Within days, anxiety relief is usually pronounced and sustained.

The patient with "high level anxiety" who cannot cope

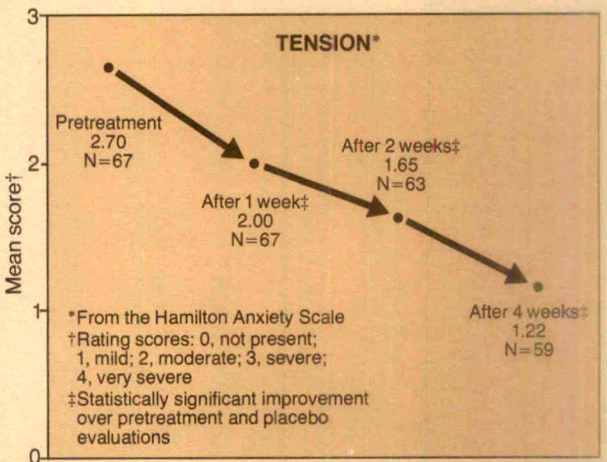


Life's stressors may produce a level of anxiety that blocks a patient's normal coping responses. Preoccupied with his symptoms, the patient may be unable to open up to psychotherapy. In such cases Valium (diazepam) can achieve a rapid response, which helps the patient participate. Reassured by the rapid anxiety relief, the patient becomes more amenable to therapy and better able to help himself. When anxiety has reached manageable levels, Valium should be discontinued.

ROCHE

The patient with anxiety accompanied by somatic symptoms

A recent collaborative study [2] confirmed what physicians throughout the world have found in clinical practice: Valium (diazepam) promptly relieves psychic *and* somatic anxiety symptoms. As anxious mood and tension diminished, the bodily symptoms that so often accompany the anxious state were significantly reduced.



2. Data on file, Medical Department, Hoffmann-La Roche Inc., Nutley, New Jersey 07110

The patient with anxiety expressed through functional symptoms

When intense anxiety triggers CNS-mediated defense reactions, patients experience physiological effects they may interpret as organic illness. The prompt response obtained with Valium (diazepam) can successfully counter this anxiety-linked arousal. The rapid initial response to Valium reassures the patient and helps reduce the level of CNS reaction. This helps the patient understand the reasons for his functional disorders and reduces his preoccupation with his physical condition.

Three dosage strengths, all in scored tablets, make it easy to adjust dosage up or down as needed. In patients prone to anxiety at bedtime, adding an *h.s.* dose to the *b.i.d.* or *t.i.d.* regimen reduces anxiety enough to permit sleep.

Valium is usually well tolerated. Side effects more serious than drowsiness, fatigue or ataxia are rare. Of course, as with most CNS-acting medications, patients should be cautioned against drinking alcohol or driving while on Valium therapy. Periodic reassessment of such therapy is also recommended.

VALIUM® (diazepam) IV

2-mg, 5-mg, 10-mg scored tablets

UNTIL THE PATIENT CAN COPE AGAIN

Please see following page for a summary of product information.

VALIUM®
(diazepam)

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

The effectiveness of Valium (diazepam) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should periodically reassess the usefulness of the drug for the individual patient.

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

a consideration beyond efficacy alone...

Infrequent akathisia and other disabling extrapyramidal effects...

The rapidly rising readmission rate among discharged psychotic patients is mainly due to noncompliance with antipsychotic drug therapy. And this, in turn, may be largely attributed to disabling extrapyramidal side effects, notably akathisia.[1]

Although extrapyramidal effects are characteristic of antipsychotic agents in general, with Mellaril (thioridazine) such effects are infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided. Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

Extrapyramidal Effects of Selected Antipsychotic Agents*[2]

DRUG	EXTRAPYRAMIDAL EFFECTS
Chlorpromazine	Moderate
Perphenazine	High
Prochlorperazine	High
Fluphenazine	High
Acetophenazine	Moderate
Trifluoperazine	High
Chlorprothixene	Moderate
Thiothixene	Moderate
Haloperidol	High
MELLARIL® (thioridazine)	Low

*Based on antipsychotic dosage ranges

Mellaril® [thioridazine]

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP
CONCENTRATE: 100 mg per ml

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.
Store and dispense Concentrate below 86°F; use tight, amber glass bottle. Just prior to administration, Concentrate may be diluted with distilled water, acidified tap water, or suitable juices; preparation and storage of bulk dilutions is not recommended.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.
It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

Issues Critical to the Survival of Community Mental Health

BY JONATHAN F. BORUS, M.D.

The author delineates some of the critical issues that face community mental health, with the opportunity for either growth and further development or regression into a decentralized type of custodial care. These issues include clarifying boundaries and priorities, caring for chronically ill deinstitutionalized patients, providing differentiated care, collaborating with the community, relating to the rest of psychiatry and medicine, defining the community psychiatrist's role, maintaining psychiatric manpower, undertaking evaluation research, and achieving stable funding. Psychiatry's response to these issues will help determine the resolution of this crisis and the future viability and direction of community mental health.

COMMUNITY mental health (CMH), the population-based, prevention-oriented, primarily publicly funded mental health service delivery system that has grown up in the United States over the last 14 years, faces a crisis in its development. Increasing political and scientific criticism has been coupled with significant funding cuts at a time when this "adolescent" still needs considerable support and resources to develop in a healthy manner (1–5). The national climate of therapeutic optimism, societal demand for distributive justice, and personal presidential interest that created CMH in the early 1960s changed dramatically during 8 years under administrations openly hostile to public mental health services (6). Today we again have a President who has a personal interest in mental health and who has appointed a commission to make recommendations mapping out the directions of mental health delivery for the foreseeable futu[illegible] of these deliberations will determine whe[illegible] ceives the resources necessary to rese[illegible] through further differentiation into a [illegible] and responsive public delivery system. [illegible] will die a slow death of fiscal starvation[illegible] attempts to bring some of the critical issu[illegible] lems facing CMH into sharper focus for [illegible] during this period of reassessment and pl[illegible] ture mental health services.

Dr. Borus is Assistant Professor of Psychiatry, Harvard Medical School, and Director of the Psychiatric Residency Training Program and the Subspecialty Training Program in Social and Community Psychiatry, Massachusetts General Hospital, Boston, Mass. 02114.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration training grant MH-14124 from the National Institute of Mental Health.

THE BOUNDARY PROBLEM

CMH has been frequently criticized f[illegible] boundaries and priorities, with allegatio[illegible] tried to be all things to all people and has [illegible] the mental health professions by becom[illegible] areas in which it has no expertise [illegible] boundary problems stem in part from th[illegible] mism of the early 1960s in which CM[illegible] marching into the community as the "[illegible] tack" (President Kennedy's words) on th[illegible] mental illness and mental retardation (8[illegible] this crusading atmosphere, federal leg[illegible] dated CMH to do the impossible, that [illegible] serve all citizens with defined mental illne[illegible] for treatment within a large (75,000–200[illegible] population-defined geographic area, but [illegible] mentally ill in the community who do no[illegible] treatment, prevent mental illness in the [illegible] in the community, and improve the me[illegible] the rest of the population. Parenthetical[illegible] prising that society sent psychiatrists t[illegible] the theoretically interesting but clinic[illegible] concepts of catchmented responsibility, [illegible] cus, prevention orientation, and consum[illegible] tion. Psychiatrists, always on the [illegible] fringe," were mysterious enough to be s[illegible] enough to go, and, as shown in recen[illegible] enough to disown if things did not work[illegible]

This march into the community too[illegible]

0002-953X/78/0009-1029$0.60 © 1978 American Psychiatric Association

some exciting areas of productive consultation and collaboration with such groups as educators, urban planners, and police. However, by the late 1960s some CMH professionals began to lose perspective and, instead of providing needed services, made direct attempts under the banner of prevention to change society by organizing protests against social ills, telling community leaders what to do, and involving themselves in other activities clearly beyond their professional expertise. They had deceived themselves into trying to fulfill the public illusion that psychiatry could solve societal problems; as is usually the case, public disillusionment with CMH followed shortly thereafter when the impossible could not be delivered. Unfortunately, in the minds of many prominent psychiatrists and politicians these misguided ventures of the 1960s persist in overshadowing the majority of CMH efforts aimed at improving the quality and quantity of direct mental health services in the country (9).

In the late 1970s, it is essential that CMH sharpen its boundaries, delimit its priorities, and increase its accountability if it is to survive. As the publicly funded mental health service delivery system, it must recognize its primary obligation to serve first those patients with the most serious and debilitating illnesses whom the public sees as most distressed and distressing. CMH has failed when it has not implemented a network of community-based services for such patients, and it has been most successful when it has increased psychiatry's links to the previously underserved through a realistic delivery system of mental health services (5). Although CMH professionals should contribute their knowledge of normal and pathological behavior to discussions of social issues important to the community (e.g., education, race relations) (10, 11), in the future they must scrupulously decline acceptance of tasks outside their areas of expertise, regardless of societal urgency or importance.

CARE FOR CHRONICALLY ILL PATIENTS

Community mental health centers (CMHCs), originally proposed as alternatives to care in state hospitals, have been criticized for avoiding the difficult task of providing the therapeutic services necessary to maintain severely ill and disabled psychotic patients in the community (1, 2, 12–14). CMHCs have often been unprepared or unwilling to meet the comprehensive service needs of the large number of chronically ill patients returned to the community as a result of the public policy of deinstitutionalization. This failure has resulted in inadequate care for these patients and citizen backlash deleterious to reintegrating patients into the community (15, 16).

If deinstitutionalization is to be more than a regressive shift of patients from the back wards to the back alleys, it will be a very expensive undertaking in both human and monetary costs. As detailed elsewhere (17, 18), meaningful deinstitutionalization necessitates the provision of a broad spectrum of services to reintegrate the patient into the community. These include the predischarge services of discriminate evaluation and individual patient selection for return to the community, assessment of family and community readiness for the patient's return, and preparation of the patient for the transition from hospital to community. Requisite services in the community include provision of basic subsistence needs, provision of sheltered living facilities, maintenance and monitoring of psychoactive medications, provision of appropriate mental health care, provision of meaningful ways to occupy time, and provision of supportive services to the patient's family and community. Recent federal legislation mandates CMHCs to provide posthospital aftercare as an "essential service" and to coordinate the multiple sources of financial, housing, mental health, and medical care needed by these patients (19, 20). CMH professionals should therefore collaborate with citizens' groups to insist that responsible government and political officials make necessary support services available *before* hospitals are closed and large numbers of patients are returned to the community.

PROBLEM DIFFERENTIATION AND SERVICE FIT

CMH has also been criticized as "second-class psychiatry" that substitutes quantity for quality care. Under the pressure of serving the entire population, evaluations are frequently relegated to the least experienced clinicians, and a limited range of therapeutic services are offered in volume. The essence of "first-class psychiatry" is treatment predicated upon the correct evaluation of each patient's problem and application of a differentiated therapeutic response to fit that particular problem (21). CMHCs should therefore use their most experienced clinicians (usually psychiatrists) in the evaluation process to interview or closely review each new patient in sufficient depth to responsibly pinpoint the diagnostic problem.

Accurate evaluation must be followed by fitting the problem to the best possible treatment alternative. This necessitates the availability of a wide variety of treatment and therapist alternatives; a CMHC that offers just support, just medication, just crisis intervention, or even just psychoanalysis to all of its patients is inherently providing second-class treatment. All treatment alternatives do not have to be available in one setting; a coordinated network of services (described below) can be established in which different therapeutic services are provided in different locations. CMH professionals should alert citizens' groups and politicians to the possible conflicts between quality and quantity care, i.e., the provision of a large quantity of inappropriate therapies is not helpful to patients and a smaller volume of service may be necessary to foster a higher quality and broader spectrum of treat-

ment alternatives that promote appropriate problem-treatment fit. Although cognizant of the urgent need to respond better to deinstitutionalized and chronically disabled patients, publicly funded CMHCs should also continue to devote some of their resources to treating patients with less severe disorders, consulting with community care givers, and undertaking prevention/education programs to avoid citizens' stigmatizing perception of them as "community mental illness centers" to be used only as a last resort.

RELATIONSHIP TO THE COMMUNITY

CMH has experienced confusion with the concept of and difficulties in its contacts with the community during its developmental years. The concept of a community as a cohesive group of citizens with common values, a shared sense of destiny, and natural support systems rarely fits the federally defined geographic areas with 75,000–200,000 inhabitants (22). These large "catchmented communities," often created de novo to acquire federal funding, usually include several smaller aggregates of citizens who have little in common with each other and disparate points of view. Many CMHCs have established satellite delivery sites to attempt to respond to the specific needs of these smaller subcatchment areas.

Some CMH programs have been more interested in enlarging the domain of a parent institution (e.g., university, hospital) with new buildings and staff than in working with the community to improve mental health service delivery. Although most centers have some sort of consumer-citizen board, these boards are often controlled by center staff and do not have the power of advice or consent in important policy issues. Community representatives too often are sent the double message that their views are of utmost importance—as long as they are in agreement with those of the professionals. In recognition of this bind, 1975 legislation requires that policy-setting citizens' boards be an integral part of any new CMHC that receives federal funds (19).

Task-oriented collaboration and shared control between consumers and professionals according to their differential expertise is a difficult but critical goal in these fiscally troubled times for CMH. Citizens, not psychiatrists, have the political muscle to let their legislators know that votes depend on continued support of scarce but vital resources for CMH. Citizen support is crucial to any plan to return deinstitutionalized patients to the community; citizens' boards can be key to the success of community education programs and can communicate to politicians the importance of having support services in place for deinstitutionalized patients to avoid community disruption. Since all of the "essential services" dictated by federal legislation cannot be provided to all who need them within any one catchment area, citizen participation is essential in deciding program priorities. CMH professionals should welcome the opportunity to share representatives the dilemma of having sources to meet an unlimited mandate comitant painful task of deciding what ser be provided and which patient needs served.

RELATIONSHIP TO MEDICINE

The growth of CMH has coincided wit psychobiological research, and in recer field of psychiatry has started to return to roots, led by collaborative efforts of psyc other physicians in the general hospita coordinated comprehensive health care psychiatrists have seen CMH moving in direction, away from and outside of me traditions, to form a separate power ba competition between CMH and other se chiatry for extremely scarce research and sources has caused much antagonism, an tings community psychiatrists are in dan their ties to and support from the genera

An evolutionary step for CMH, whic crease its ties to the rest of psychiatry patient care, would be for it to spearhead return to medicine at the primary care lev attention and legislation focus on impro tion's capacity to provide accessible p care for all citizens (24), it is important that CMH systems have been providing tal health care in the community for the (25). Rather than continuing to use freest ties isolated from general health services extend the coordination of medical and care begun in the general hospital to the prehensive primary care in the commun

Attempts at providing such coordina care have been made in neighborhood he and health maintenance organizations in of the country (25–28). Recent studies of programs in neighborhood health center this locus has several advantages for the primary mental health services (25, 29–3 clude greater accessibility and acceptabil sultant increased utilization of mental he when they are offered as part of general a local setting; better case-finding, referra up care when medical and psychiatric ca together under the same roof; and impro cation, consultation, collaboration, and among providers, fostering coordinatio fragmentation of care.

These studies also demonstrate the nee progress beyond the limits of a building-b system. The initial federal legislation fun struction of large CMHC buildings, an grams have attempted to provide all types care *in* this setting (the "edifice com

planners should shift their focus from the self-sufficient CMH *center* to a CMH *network* of services. In the latter system primary mental health services, provided as part of primary health care in the community, would be coordinated with more expensive and specialized secondary and tertiary level interventions (e.g., inpatient care, long-term insight-oriented psychotherapy) offered in freestanding CMHCs, general hospitals, and mental hospitals.

THE PSYCHIATRIST'S ROLE IN CMH

The role of the psychiatrist in CMH is often as ill-defined as the field's boundaries. Some psychiatrists have advanced beyond their area of clinical competence to assume major administrative roles, often with disastrous consequences. Most psychiatrists, as their centers' senior clinicians and only physicians, divide their time between direct service and indirect supervision and teaching of other clinicians. Even this role as clinical leader has been questioned in centers where sharing of expertise and multidisciplinary role overlap have degenerated into false egalitarianism. Some ask why the psychiatrist is paid more than nonpsychiatrist professionals who *could* be the psychotherapists, administrators, supervisors, and teachers; even medical evaluation and psychopharmacological prescription could be done through consultative referrals to primary physicians. False egalitarianism thrives when the psychiatrist's role is not clearly defined, leaving him in an uncomfortable, defensive position within his CMHC.

When such conditions exist, psychiatrists should diplomatically point out that their rigorous medical and psychiatric training, extensive leadership experience in patient management, and ultimate legal responsibility for patient care differentiate them from other clinicians. Although any separate part of the psychiatrist's role might be provided by another professional, the combination of medical, psychological, and management expertise and skills in one person makes him or her an invaluable resource. When the psychiatrist's access to a more lucrative private practice is also considered, the marketplace assigns him or her a higher salary than other CMH professionals; however, as a center's most expensive professional resource, psychiatrists have the obligation to question whether their costly expertise is being used most effectively.

Psychiatry must do a better job in preparing its trainees for the clinical, teaching, and administrative aspects of the community psychiatrist's role. Specific theoretical and practical experiences in community psychiatry should be a core part of residency programs, including opportunities to collaborate with, supervise, and teach other CMH professionals. Medical and neurological skills relevant to the diagnostic needs of the CMHC and consultative-collaborative work with primary physicians must be refined in residency training. In addition, if some psychiatrists are to administratively lead the complex, multimillion-dollar organizations that CMH delivery systems have become, there should also be subspecialty training programs that add specific executive-administrative skills to these psychiatrists' clinical expertise (32).

MAINTENANCE OF PSYCHIATRIC MANPOWER

The lack of adequate and stable rewards has led to a disturbing level of turnover in CMH's psychiatric manpower. Many prominent community psychiatrists have "burned out" and left CMH in recent years. Although the absolute number of psychiatrists working in CMHCs rose by 45% between 1972 and 1976 with the opening of new centers, psychiatrists' proportionate representation has decreased 27%, dropping from 6.4% to 4.7% of all CMHC staff (33, table 20). Many young psychiatrists work in CMHCs after their training (34, 35); often, however, it is a salaried position used as a temporary stepping stone to support them while they establish more rewarding private practices. This frequent turnover of psychiatric leadership has been detrimental to many centers' level of patient care, staff morale, and sense of continuity. Improving community psychiatry training may stimulate more psychiatrists to try CMH practice after residency (36–38). However, to stabilize the psychiatric foundation of CMH and avoid a "drift phenomenon" in which only those psychiatrists least qualified to work in other modes of practice perform its long-term service and leadership roles, CMH's unstable and inadequate reward system must be corrected.

The stability and mix of monetary, academic, developmental, and altruistic rewards often determine a psychiatrist's long-term satisfaction with his or her practice (39). A community psychiatrist usually earns between one-half and two-thirds of the income available for a comparable number of hours' work in private practice, and a recent study found this low fiscal return a definite deterrent to the long-term maintenance of psychiatrists in CMH (40). Without substantial federal help it will be difficult to raise CMH salaries to competitive levels, and many community psychiatrists accept the fact that they must supplement their income by private practice. However, more difficult to tolerate is the frequent intimation by political figures and the media that community psychiatrists who spend extra hours of their own time in private practice to supplement their low public salaries are in some way robbing the public purse, since all of the limitless needs of the citizens in their public catchment area have not yet been (and never can be) fully met. To decrease this distortion, a major public educational effort by the American Psychiatric Association is needed to put the monetary rewards of CMH practice into perspective.

Academic affiliations are extremely helpful in recruiting qualified psychiatrists to CMH by providing university appointments, intellectual stimulation, and

continuing education. However, academia specifically rewards those who conduct and publish research, while rarely recognizing clinical service and teaching in the community with academic promotion. Community psychiatrists usually have to "bootleg" their academic efforts from service time, and medical students and residents, noticing that there are few full or associate professors in CMH, are led to seriously question whether CMH is a respected and valued practice alternative. To keep psychiatrists attracted by the academic tie, CMH programs should designate time for research away from direct service provision to make the evaluation of CMH theory and practice a legitimate part of the psychiatrist's role.

The community psychiatrist's role can provide a variety of opportunities for personal and professional growth. With the nationwide demand, psychiatrists can usually find CMH positions in locations that satisfy the needs of their family and lifestyle. In his or her work the community psychiatrist has opportunities to further develop basic psychotherapeutic, consultative, and clinical leadership skills as well as any teaching, research, or administrative talents he or she may possess. However, if the psychiatrist's multiple skills are not used effectively and he becomes just the "prescription signer" of CMH, he will stagnate and soon begin to consider the possibility of doubling his income by providing such direct services in private practice.

Altruism is a major benefit available in CMH to psychiatrists who enjoy treating patients with the greatest disabilities and needs. However, it is a painful experience for altruistic psychiatrists who work in the public sector serving the chronically ill and debilitated to find themselves the targets of projected anger from a society ambivalent about the costs and difficulties of caring for this patient population. Under the pressure of the public arena, altruism alone is rarely sustaining over extended periods of time; if the other types of rewards are inadequate, altruism wears thin and "burnout" begins as the community psychiatrist discovers that the reverse side of altruism is masochism. In summary, if a more adequate and stable mix of rewards does not become available in CMH, the best and the brightest psychiatrists will not enter or stay in the field.

PAUCITY OF EVALUATION

Insufficient evaluation has contributed significantly to the political and scientific criticism of CMH and has made it extremely vulnerable to cuts in funding (41, 42). Realistic reasons that little careful evaluative research has been conducted to date include CMH's action orientation and constant demand for service, which allow little time for evaluation; the complexity and dynamic state of communities that afford almost none of the laboratory's possibilities for controlling some variables to study others; and frequent public opposition to research that is perceived as exploiting the community. Despite these obstacles it i[illegible] a scientific and a fiscal necessity for CMH [illegible] als to examine the field closely (43, 44).

Evaluation research in CMH should fol[illegible] hierarchy of studies (45). It should first ass[illegible] ment system's effectiveness in decreasing p[illegible] morbidity in the patient, his family, and t[illegible] nity at large; it should then assess the syste[illegible] sibility and utilization; and it should asse[illegible] tem's costs compared with similarly effect[illegible] cessible alternatives (45). Outcome [illegible] investigate the long-term impact of comm[illegible] ment compared with treatment in an insti[illegible] ting are essential to understand the proce[illegible] stitutionalization. Although existing studie[illegible] community treatment may inhibit chronici[illegible] psychotic patients, additional studies are nec[illegible] sess whether community treatment re[illegible] chronic disabilities of patients institutio[illegible] many years. Another outcome too frequ[illegible] sessed is patient satisfaction with the thera[illegible] ices offered by the CMHC. CMHC utiliz[illegible] should be compared with those of other de[illegible] tems and with national rates to assess acce[illegible] care, and patient demography should be s[illegible] determine whether CMHCs treat patient[illegible] lems left unserved by other care provide[illegible] the comparative costs of *quality* care in diff[illegible] ment locations (neighborhood health ce[illegible] standing CMHCs, general hospitals, psych[illegible] tals) should be ascertained, remembering[illegible] cost, poor-quality care is no bargain.

These extensive research needs will requ[illegible] es in the accessibility of research expert[illegible] amount of earmarked evaluation funds fro[illegible] ty, state, and federal sources. Most CMHC[illegible] ther the in-house investigators nor the [illegible] committed funds to undertake these essen[illegible] by themselves and will require both help [illegible] ued government pressure in order to acce[illegible] (46).

UNSTABLE FUNDING

Underlying each of the previous probl[illegible] the need for a more stable economic base [illegible] survive. It has been disheartening to profe[illegible] catastrophic to patients to see program[illegible] years of painstaking work decimated in a [illegible] by withdrawal of government funding [illegible] placed "fiscal restraint" or political whim[illegible] rect service provision must move away fr[illegible] nerability of total dependence on annual[illegible] ated, politically controlled funding from [illegible] sources. President Kennedy's prediction [illegible] support for mental health services would [illegible] essary for a few years until private insura[illegible] nisms were developed to pay for such servi[illegible] not been realized, and we will have to w[illegible]

tional health insurance is enacted to allow everyman to buy his own mental health services.

A fee-for-service, free choice, "voucher" type of national health insurance would provide CMH delivery systems with the ultimate evaluation in which they would either succeed or fail on the open market. The CMH systems that have worked well with their communities to develop services and programs uniquely suited to their citizens' mental health needs will probably continue to be used by a broad spectrum of consumers and become financially stable. Those which have offered nothing unique to their communities will be bypassed in preference to private practitioners by all but the least desirable patients. Since most national health insurance proposals focus primarily on reimbursement for direct services, public funding will continue to be needed through direct subsidy or capitation mechanisms to support the crucial CMH functions of training, evaluation research, consultation and education, and coordination of health and mental health services.

CONCLUSIONS

This paper has delineated some of the critical issues that face CMH with the opportunity for either growth and further development or regression into a decentralized type of custodial care. Psychiatry's response to these issues will help determine the resolution of this crisis and the future viability and direction of CMH.

Foundations' Fund Prize for Research in Psychiatry

The American Psychiatric Association is inviting submissions for the second annual Foundations' Fund Prize for Research in Psychiatry.

Candidates for the prize should be citizens of the United States or Canada and should be nominated by a sponsor. Sponsors should be members of the American Psychiatric Association. Members of the prize board are excluded from submitting nominations.

The *sponsor* should submit a supporting letter justifying the nomination in detail and summarizing the nominee's research accomplishments.

The *nominee* should submit the following:

1) An up-to-date curriculum vitae,
2) An up-to-date bibliography,
3) A group of representative and thematically linked papers or books published (or accepted for publication) in English and dated within 10 years of the deadline for submission, and
4) A summary statement written by the nominee that emphasizes the principal theme or themes running through the work and its internal cohesiveness and consistency.

Six copies of each entry should be submitted to Joel J. Elkes, M.D., Chairperson, Foundations' Fund Prize Board for Research in Psychiatry, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but cannot be returned. The award will be presented at the Convocation of Fellows at the APA annual meeting in May 1979.

The deadline for submission is December 1, 1978. Any entry received after that date will automatically be entered for consideration for the 1980 award unless withdrawn by the nominator or candidate.

Current Medication Use and Symptoms of Depression in a General Population

BY THOMAS J. CRAIG, M.D., M.P.H., AND PEARL A. VAN NATTA, M.A.

In a community survey, 41.8% of 771 men and 60.2% of 1,059 women reported having used one or more medications in the 48 hours before the interview. The use of medications and the number of medications used increased progressively with age among both men and women. Respondents who used four or more medications included significantly more high scorers on a depression checklist than those who used fewer medications. The group of women who used minor tranquilizers and sedatives included significantly more high depression scorers than those who did not. Among both sexes, those scoring in the depressed range who were receiving psychotropic medication tended to be taking minor tranquilizers or sedatives.

STUDIES of medication use in the past decade have used data derived from the prescribing habits of physicians (1–4) and from surveys of general and patient populations (5–9). The time periods for which this information has been collected range from one month to one year (6–8), and analyses have generally been restricted to either a limited number or type of drugs (e.g., psychotropic medication) (1–7) or a relatively limited purpose (e.g., prevalence of adverse reactions) (9).

The present study is unique in several respects: 1) inclusion of all medication use reported by respondents in a community survey, both prescription and nonprescription, 2) focus on current drug use (i.e., within the 48 hours preceding the interview), and 3) examination of the relationship between current drug use and symptoms of depression. The last aspect is particularly important in view of reports indicating that, in populations of medically ill patients, depression is frequently underdiagnosed and is inappropriately treated even when recognized (4, 10–12).

At the time this study was done Dr. Craig was Assistant Professor, Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, Md. He is now Director, Admissions and Training Unit, Rockland Psychiatric Center, Orangeburg, N.Y. Ms. Van Natta is Research Associate, Department of Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md. Address reprint requests to Dr. Craig at 40 Woodbine Rd., New City, N.Y. 10956.

This study was supported in part by contract HSM-42-71-31 from the National Institute of Mental Health.

METHOD

The present data are taken from an interview survey carried out in Washington County, Md., during 1972–1974 in conjunction with the Center for Epidemiologic Studies (CES) of the National Institute of Mental Health (13, 14). The major emphasis of the survey was on depressed mood and related symptomatology. One depression rating scale, the CES-D, was included (15). The CES-D has a potential range of 0–60, obtained by summing the weighted number of days of the week preceding the interview during which the respondent experienced the feeling described by each item (16).

A cutoff score of 16 or above was found to best distinguish between depressed and nondepressed psychiatric patients (17)[1] and was the cutoff score used in the present study to identify individuals with high levels of symptoms of depression.

As an index of recent medication use, the respondent was asked, "In the past 48 hours, what medicine or drugs have you taken?" The specific medications reported were then listed along with the reasons for taking them. Although it was not possible because of the nature of the study to stimulate the respondents' recall as has been done in other studies (e.g., with charts or lists) (6, 7, 9, 18), the interviewers were asked to verify drugs whenever possible by asking to see the bottles.

The questionnaire was administered in two versions. The earlier version was administered to 741 subjects in this study (an additional 930 subjects had been given the first questionnaire before the medication question was included), and the later version was administered to 1,089 subjects. None of the differences in the two versions of the questionnaire directly affected the CES-D or the medication question, and extensive analyses revealed no significant differences between responses on the first and second versions. For this reason, the samples for both versions are combined in the present analysis. The 1,830 interviews represent a response rate of 80.5% for the first version and 75% for the second version.

All of the interviewers were middle-aged women, which may have biased the information obtained. The extent of this bias could not be accurately estimated, but a report on the earlier version of the questionnaire

[1]Weissman MM, Sholomskas D, Pattenger M, et al: Assessing depressive symptoms in five psychiatric populations: a validation study (unpublished paper).

0002-953X/78/0009-1036$0.45 © 1978 American Psychiatric Association

(14) demonstrated no significant differences among interviewers in respondent reports of total medications used.

RESULTS

For the total population (N=1,830), 41.8% of the men and 60.2% of the women reported the use of one or more medications during the 48 hours preceding the interview. Among men, the proportion using medication ranged from a low of 23.7% among the 18–24-year-olds to 67.3% of those in the 65 years old and older age group. The corresponding figures for women were 52.1% in the 18–24-year-old group and 75.6% in the 65 years old and older category. In the 65 years old and older category for both sexes, approximately 10% of the population reported that they used four or more drugs. In the 55–64-year-old group, however, 7.0% of the men and 4.9% of the women reported using four or more medications. Among respondents reporting the use of one or more drugs, there was no significant difference between men and women either in age distribution or in number of drugs used. The distribution of CES-D scores by number of medications used (see table 1) reveals a consistent trend for men and women. Those respondents who used four or more drugs were significantly more likely to have high scores for depression than those using three or fewer ($p<.05$, chi-square test); more than 30% of the men and 40% of the women scored 16 or greater.

When all of the drug classes were examined, only two medication groups, minor tranquilizers and sedatives, showed significantly greater proportions of high CES-D scorers among users in comparison with nonusers ($p<.01$, chi-square test), both true only among women. Among men, 18.2% of those who used tranquilizers and 21.1% of those who used sedatives had CES-D scores above 16, compared with 11.0% of nonusers. In contrast, among women, 36.7% of those who used tranquilizers and 51.4% of those who used sedatives had high CES-D scores, compared with 17.2% and 17.9%, respectively, of nonusers.

The proportions of respondents with elevated (16 or more) CES-D scores who were receiving psychotropic medication are listed in table 2. Although not all respondents who scored above 16 could be considered clinically depressed and in need of treatment, it is reasonable to assume that a large proportion of them were depressed. An additional cutoff score of 30 or more is included to identify a group considered at extremely high risk of depression. In the group with scores of 16–29, the vast majority of those who were receiving any psychotropic medication were taking either minor tranquilizers or sedatives; only a handful reported using an antidepressant. In the high-risk group (scores of 30 or more), this predominance of tranquilizer-sedative use is even more striking.

Among the total group of respondents with scores of 16 or more, only 1.1% of the men (N=87) and 3.5% of the women (N=201) were using an anti[illegible] the time of the survey.

TABLE 1
Number of Medications Used by 771 Men and 1,[illegible] CES-D Scores

Item	CES-D Sc[illegible] 0–15 N	%	16–29 N	[illegible]
Number of medications used by men				
None (N=449)	401	89.3	44	9[illegible]
1–3 (N=297)	266	89.6	27	9[illegible]
4 or more (N=25)	17	68.0	7	2[illegible]
Number of medications used by women				
None (N=421)	357	84.8	51	12
1–3 (N=590)	474	80.3	89	15
4 or more (N=48)	27	56.2	15	31

DISCUSSION

Several characteristics of the present [illegible] differentiate it from previous studies [illegible] use. The site of the survey is a county [illegible] Maryland whose population is largely wh[illegible] white) and relatively equally divided be[illegible] (40% reside in Hagerstown, a city of [illegible] 40,000) and rural (40%) populations. Its [illegible] sphere might be defined as typical of "[illegible] ca," and the drug use patterns would [illegible] differ to some extent from those found [illegible] and, especially, western areas (6–8).

The relatively short time interval [illegible] which the respondent was queried was [illegible] to maximize recall and to determine, as [illegible] sible, current drug use. In its brevity, [illegible] fers from studies that covered time perio[illegible] month to one year (6–9). Because the p[illegible] the present survey was on depression, [illegible] time could be devoted to detailed inqu[illegible] drug use, as has been the practice in oth[illegible] 9, 18). Several authors have commented [illegible] tive underestimates that may occur in [illegible] (18, 19). Our belief was that the short d[illegible] and the ascertaining of exact informatio[illegible] minimized this bias, but we have no direc[illegible] suring its effect on the present data. He[illegible] parison of the rates obtained in this surve[illegible] data from surveys covering longer time [illegible] to support our assumption.

For example, Parry and associates (7) [illegible] the northeastern United States over a [illegible] 16% of men and 33% of women used p[illegible] nonprescription minor tranquilizers an[illegible] or hypnotics. Our findings were 6.8% [illegible] 12.6% for women in a *48-hour period*. S[illegible] hold true for the other psychotropic [illegible]

TABLE 2
Type of Psychotropic Medication Taken by 771 Men and 1,059 Women, by CES-D Scores

	CES-D Score											
	Men						Women					
	0–15 (N=684)		16–29 (N=78)		30 and Over (N=9)		0–15 (N=858)		16–29 (N=155)		30 and Over (N=46)	
Type of Medication	N	%	N	%	N	%	N	%	N	%	N	%

Stimulant	0		0		0		3	0.3	0		0	

parison of our data with those of Seltzer and associates (8) and Greenblatt and associates (5) further strengthens our assumption that we minimized underestimation. In the former (8), a range of 7.6%–11.4% of men and 14.8%–20.6% of women reported using psychotropic drugs in the previous year, and in the latter (5), 15% of men and 25% of women reported psychotropic drug use in the three months before the study.

Our overall findings of drug use are comparable to those reported in other studies of medication use in patient populations in that drug use tends to increase in both amount and frequency with age in both sexes (4–9). In addition, women of any age tended to be more likely to use drugs than men. As has been pointed out elsewhere (7), the latter may be a relatively deceptive finding, especially as it relates to psychotropic drugs, because we also found that the men tend to use alcohol significantly more often than women (20). A finding that has not been stressed in previous studies, however, is the observation that when only users of medication are examined, the age distribution and distribution of number of drugs used were essentially the same in men and women. This suggests that although more women than men use drugs, there is no significant sex difference among medication users in overall pattern of drug use (by chi-square test).

Another striking finding is the fact that more than 40% of the men and 60% of the women surveyed had used at least one medication during the 48 hours before the interview. These figures exceed those of Seltzer and associates (8), who reported a rate of 24.4%–26.1% among white men and 44.6%–46.3% among white women in the year before the interview. Particularly important is the high level of drug use among the elderly (those 65 years old and older). In this age group, 22.1% of the men and 27.3% of the women reported taking three or more drugs. This very high prevalence of current medication use emphasizes the importance of obtaining complete medication data in clinical medicine to avoid the possibility of introducing adverse drug interactions (9, 21).

Table 1 shows that the percentage of people with symptoms of depression was significantly greater among individuals taking four or more medications ($p<.05$, chi-square test). Only two categories of medication were associated with a significantly higher proportion of high CES-D scorers for users than nonusers (minor tranquilizers and sedatives) ($p<.01$), and this was true only among women. This finding is of particular importance in view of the reports that depression, when recognized, is frequently treated with these categories of drugs, which have been shown to be of little benefit in the treatment of depression per se (although they may assist with such specific symptoms as insomnia) (10, 11, 22). In addition, a 1972 report (23) suggested that high doses of diazepam, the most frequently used minor tranquilizer in this study, may cause depression in nondepressed individuals. Furthermore, antidepressants have been shown to be specifically effective treatment not only for symptoms of depression but for anxiety as well (22, 24).

Perhaps the most disquieting data in the present study relate to the recognition and treatment of depression. Several studies (4, 25) have emphasized the prevalence of symptoms of depression among the medically ill. Further, several studies (26–28) have emphasized the need for early recognition and treatment of depression as a preventive for such negative outcomes as suicide and disability.

Since analysis of drug pairs revealed very little overlap in the use of psychotropic drugs (2 respondents who used antidepressants were also using minor tranquilizers, and 4 who used sedatives were also using minor tranquilizers), the data in table 2 represent virtually mutually exclusive categories. Approximately 14% of the men and 29% of the women whose CES-D scores were in the 16–29 range were using psychotropic medicine. Corresponding figures for CES-D scores of 30 or more were 22.2% for men and 39.1% for women, suggesting that psychological distress was identified and currently being treated in a substantial proportion of these groups. Even allowing for the possibility that some of these individuals may have had medical illnesses that precluded the use of antidepressants, the proportion using antidepressants in these groups was minuscule. Furthermore, the data suggest that high scorers were likely to be disproportionately older and more medically ill than the general popu-

lation, factors that substantially increase the risk of suicide.

In view of these rather startling findings, it is imperative that steps be taken to improve the recognition of depression among physicians and the general public. In addition, it is clearly the task of the medical profession to educate its members, especially those in nonpsychiatric practice, to the specific treatment of depression. At the present time, if depression is recognized at all, it is most likely to be treated with nonspecific remedies (minor tranquilizers and sedatives) that, at best, offer merely palliative symptomatic relief and, at worst, may intensify the distress they are intended to treat.

The Military Family Syndrome

BY DON M. LAGRONE, M.D.

The author reviewed the case records of 792 children and adolescents seen in a military clinic over a two-year period. His data suggest that the incidence of behavioral disorders was higher in this clinic than in a civilian mental health center. Seven problem areas common to records in which a behavioral disorder was diagnosed were found. The author suggests that the behavioral problems of the group studied represent a process of acting out in the rigid, autocratic system of the military. He also suggests that an approach using systems theory and modified goals may be more helpful in dealing with problems of military families than the traditional individual approach.

FOR TWO YEARS (from 1974 to 1976) I was a member of a military child and adolescent mental health team serving families living on a large military base in the Midwest. I was somewhat surprised and puzzled by the large number of behavioral problems referred to our service and by the frequency with which certain themes appeared in the interaction of these families. In an attempt to understand the reasons for these phenomena, I first reviewed the literature and then reviewed the case material itself. In this paper I will present my findings and conclusions.

LITERATURE REVIEW

Little has been written about military families. Such authors as Cretekos (1), Bey and Lange (2), Gonzalez (3), Pearlman (4), Crumley and Blumenthal (5), and MacIntosh (6) have reported the intrapsychic conflicts of wives and children of military fathers absent from home. As in grief reactions, anger, mourning, and guilt are predominant in these wives and children. Crumley and Blumenthal (5) found that separations from the father substantially altered the development of children, particularly in superego formation and in object relations. Bloom (7) found that 24% of his patients were diagnosed as having behavioral disorders, compared with 16% in a civilian group. Among Bloom's patients, 2 out of 3 had a history of father absenteeism. Bonovich (8) described enforced family separations in the military as crisis situations, called for further study, and recommended crisis intervention techniques to deal with the problem.

CASE REVIEW

The patients whose case records were reviewed for this paper came primarily from the local families of active duty personnel residing on the base. Over the two-year period, 792 new patients were seen in the children's mental health clinic. In any given year, there are about 3,200 families with 7,400 children living on the base. Thus, new evaluations were being done for 12% of about 6,400 families and almost 6% of about 12,800 children.[1]

Of the case reports reviewed (N=792), 4% had the diagnosis of psychosis; 8%, mental retardation; 32%, behavior disorders; 7%, organic brain syndrome; 12%, neurosis; 3%, psychophysiological disorder; and 28%, transient situational disturbances. Six percent had no psychiatric diagnosis.

More than 94% of these patients were from the families of enlisted persons, compared with 6% from officers' families. At the time of referral, 12% of the fathers were absent from home.

The case review revealed seven problem areas common to many of the families and almost universally present in the case records with the diagnosis of behavioral disorders. These were the relationship the family had with the military, father absence, transiency, child-rearing methods, scapegoating, the husband-wife relationship, and resistance to treatment.

The Military-Family Relationship

To understand the military's relationship with the military family, one must understand something of the military itself. Goffman (9) used the term "total institution" to define such organizations, referring to the all-encompassing effect they have on the lives of their "inmates." Like other bureaucracies, the military is characterized by the fact that large groups of people are organized and administered by a smaller group. Ef-

Dr. LaGrone is Director, Child and Adolescent Services, Department of Psychiatry, Beaumont Neurological Center, 3240 Fannin St., Beaumont, Tex. 77701.

The author would like to thank Dr. Jon Cargill and Tsgt. Brad Billingslea for their collaboration in preparing this paper.

[1]Because of the rapid turnover of families on the base it is difficult to say that the same families would be on the base two years in a row. Estimates and averages were provided by the base public relations officer from statistics obtained by the base personnel office.

0002-953X/78/0009-1040$0.45 © 1978 American Psychiatric Association

ficiency is a key factor, and one person's infractions stand out against the compliance of the rest. When this happens, the system responds by concentrating on the individual until he or she is as compliant as the rest or is evicted from the system.

The process the military uses to force compliance is interesting and fairly well known. In total institutions, Goffman called this process "mortification":

> The recruit . . . [enters] with a conception of himself made possible by certain stable social arrangements in his home world. . . . [Stripped of this,] he begins a series of abasements, degradations, humiliations and profanations of self. (9, p. 14)

As a result of this, the "recruit's" life is managed by someone else, so that when he or she considers entering the outside world he or she may feel temporarily incapable of handling his or her affairs.

Greenblatt (10) described the government bureaucracies he worked with as materialistic paranoid systems. The same atmosphere pervades the military. Any special interest in one's job beyond the required minimum makes one suspect of individual aspiration, thus ensuring compliance and a high degree of frustration.

Another source of tension comes from the authoritative hierarchy that exists in the military. The individual's chances for being sanctioned are greatly enhanced by such a hierarchy. When sanctioned, the individual is allowed no face-saving expression; insolence is grounds for further punishment.

One other process that operates is that of the go-between (11). Confrontation is actively discouraged. Conflict between individuals is mediated by their supervisor. Problems with anyone outside the individual's unit are channeled through the chain of command. This relegates the individual to a child's status and discourages communication.

The military system binds its members tightly, and when such outside relationships as those with families are introduced a triangle is formed—with a very strong coalition between the father and the military. The family becomes the third point of the triangle, and all of the pathology that results from such triangles becomes possible. It sooner or later becomes apparent to the family that they are on the "outside." They are classified as "dependents" and have base privileges only as long as the father is on active duty or is alive. They must move from their housing on base if he is transferred or killed. For the military, the family exists only as an extension of the father, and he is expected to enforce compliance within the family. All of this serves to strengthen the father's coalition with the military and to cause the other family members to withdraw into their own systems of support.

Father Absence

Probably the most severe stress a military family faces is enforced separation from the father. In all of the case reports reviewed, the father was [illegible] the home at least once. In 12% of the ca[illegible] sought at the time of his absence. This s[illegible] important factor because in a 20-year ca[illegible] man makes an average of four overseas [illegible] as an indeterminable number of other tri[illegible] home for school, temporary duty, and [illegible] matters. When he leaves, whatever s[illegible] been to the family is gone or reduced. [illegible] lies, one of the members may become [illegible] and make requests for the father's re[illegible] families one member may take over the [illegible] father had.

In interviews with military wive[illegible] Lange (2) found that they became more [illegible] when their husbands were away. Some [illegible] interviewed said they felt little suppor[illegible] and relatives and none from the militar[illegible] supposed to be good waiting wives an[illegible] plain. When the father is transferred from [illegible] family must vacate its military housing, [illegible] and familiar places behind. The mothe[illegible] must depend on themselves, not only [illegible] existence but also for emotional suppo[illegible] the mothers of patients seen in our clinic [illegible] children to sleep with them when the fat[illegible] Others moved back into their parents' [illegible] they often encountered further stress.

Another interesting aspect of the pre[illegible] absence is that the mother quite natural[illegible] role of go-between (11). When the fathe[illegible] mother controls communication betwee[illegible] rest of the family. Some women discov[illegible] powerful position and may exaggerate o[illegible] ments or incidents that may affect the [illegible] tudes toward each other. Some contin[illegible] when the father returns.

When he returns, the father has [illegible] breaking back into the family. Many fat[illegible] cessful, become frustrated, and feel reje[illegible] dency is to repeat the cycle and ave[illegible] which only reinforces the feelings of re[illegible] sides. Many fathers secretly request t[illegible] tours and then act surprised when the[illegible] Over a period of time the family bec[illegible] tered, much like the Puerto Rican fa[illegible] York and San Juan in which the fathe[illegible] ence in the family than the children an[illegible] rary visits are only tolerated (12).

Transiency

Another problem the military family [illegible] that of the many moves it must make [illegible] ther's career—sometimes these moves [illegible] as every two years. Relationships exte[illegible] ily become shallow because there is not [illegible] develop them. The mistrust that the [illegible] feels in his job is carried to the home [illegible] their family never to disclose family [illegible]

lines of communication are down in the family, each member might find himself or herself isolated.

A kind of gypsy phenomenon is also commonly found. Military people are seen by the nearby community as transients and are often targets of mistrust and hostility. Not only does this further isolate the family and cause them to stay within the confines of the base, it presents a difficult situation for the children attending public schools. They have to break into peer groups repeatedly as the "new kid" and are often the school's scapegoats. To the military child, this kind of attention is much better than none, and he or she often begins to act out the image others have of him or her.

Methods of Parenting

The parents who came to our clinic used three methods of dealing with their children—authoritarian, democratic, and a mixed, inconsistent way. Some of the parents who felt they were democratic were actually authoritarian or inconsistent when examined. As one might expect, the greatest number of behavioral disorders, nearly 93%, came from the authoritarian families. The fathers in authoritarian families came primarily from the ranks of the enlisted, were not college educated, and were considering a career in the service. They often came from autocratic homes themselves and found the military comfortable for that reason. Often, the only model of dealing with children they knew was what they learned through their own "mortification" process. When this process is applied to a child, especially one in the adolescent years, there is bound to be difficulty.

Scapegoating

A process that is seen disturbingly often in the military is scapegoating. Since confrontation is practically prohibited and conflict is channeled through the chain of command, scapegoating is inevitable. The supervisor receives a great deal of pressure to keep his men compliant. When problems arise, as they always will in such a system, it is easier to single out someone as the cause than to examine the system. The scapegoat frequently does a great deal to contribute to this process. This model is often carried home to the family. A father who feels worried about his career may focus on one family member as the cause of family conflict.

Husband-Wife Relationship

The military husband and wife, like other couples, begin their married life with fond expectations. The husband is seen as strong and independent, and the wife is often seen as weak and dependent. Women who marry men in the military find their machismo appealing, but they are disappointed to find that their husbands are compliant, that they are tightly bound to the military and unsupportive of their needs. When the husband is assigned to duty away from home, the wife has to take over his family functions. The wife becomes more independent in this process, but the manner in which it occurs causes her problems because she feels rejected. Many times, after even one prolonged separation, an estrangement results. On the other hand, when the man returns home to find an independent woman rather than the dependent wife he left, his need to feel strong is threatened and the family system is shaken. Interestingly, some couples may remember past reunions that were pleasant; during times of family stress they will ask for a separation thinking it will solve their problems. Actually, the problems only worsen.

Treatment and Resistance

The therapist who elects to treat a military family or one of its members should keep several things in mind. The strong coalition the father has with the military probably presented the most difficult problem I had to deal with in the families who came to the clinic. Obviously, this coalition cannot be broken unless the father leaves the military or the military changes its style of relating to its members. In therapy I tried to help other family members understand this coalition and reduce their expectations of the father.

Another problem is the fact that military families are transient. The father might be reassigned in the middle of therapy. Because of this, I modified the therapeutic approach and usually saw a family for a short course of several intensive sessions aimed at uncovering conflict and helping them to understand the system. I found multiple impact therapy (13) to be a useful technique because of its effectiveness in a short period of time.

The military therapist must also be aware of the fact that the military, the local community, and the family are constantly trying to use the scapegoating process. The therapist who agrees to see the identified patient in individual therapy must consider the possibility that he or she might be assisting in scapegoating the patient. Because of this and because of the rather rigid bureaucracy within which the military therapist must operate, I have wondered if military therapists should see these families at all. Military therapists are subject to the same devices the system uses to enforce compliance in other system members, thus they might be in a rather rigid bind if they view themselves as advocates for the family. What often happens, because of pressure from the system, is that the therapist remains an advocate of the military and the scapegoating process continues.

Resistance to seeing a psychiatrist is understandably prevalent among military families. Officers seem to be more reluctant to involve themselves than enlisted men, except for those with more investment in the system. Only 6% of the cases reviewed were from the families of officers on active duty, and fewer actually became involved in the recommended treatment. Almost all of the officers seen expressed a concern for the privacy of their records. Some of their concern reflects the general paranoid atmosphere, but some of it is based in reality; their records are often available for review.

CONCLUSIONS

The data on the 792 patients seen in this military clinic were compared with those from a civilian clinic, the Wichita Falls Mental Health-Mental Retardation Center in Wichita Falls, Tex. The comparison showed that the diagnosis of behavior disorders was made more frequently in the military clinic. Bloom (7) reported a similar finding. Other authors (1–6) have tried to explain the problems that occur in military families by describing intrapsychic defects resulting from such situations as father absenteeism. After working with several hundred cases of behavior disorders, I came to feel that an explanation based on an intrapsychic model is inadequate. Behavior does not have to be a function of individual defect but may express attitudes developed in pathological systems.

It is possible, but unlikely, that the military clinic sees more patients because its facilities are more available. Compared with a population in Great Britain in which the economic availability of services was similar (14), the incidence of behavior disorders in the case records reviewed here was still much higher. In addition, compared with the estimate that 10% to 12% of the general population of children in the United States have emotional problems and need treatment (15), the experience in this military clinic of actually evaluating almost 12% of the families on the base over a two-year period is notable. Other factors, such as geographic availability and educational level of the population, must be considered, but it is questionable how really important they become in a paranoid system with so much resistance toward psychiatric involvement.

When military families seek help, the total system from which they come must be considered, and the therapist must also be aware of the system in which he or she operates. In military families the father is strongly joined with the military and becomes its agent within the family. The rest of the family withdraw from him partly out of necessity and partly out of anger, and there are feelings of rejection on both sides. The father relies more and more on military support and the family on themselves, and the system spirals ever onward. Johnson and Szurek (16) described a process they termed "acting out," and I feel this is a helpful way of viewing these families. In an attempt to get the father back into the family, the mother might exaggerate or distort a child's behavior and might covertly or even overtly encourage delinquent behavior. The children, many of whom feel alienated by the rigid class structure of the military, pressure from the community to act out, resentment of the father's autocratic methods of dealing with them, and the same anger and powerlessness their parents feel, actively respond to the family pressure to act out.

That there are problems within military families is without question. The incidence of alcoholism is high (17). The incidence of child abuse is five times higher than the national rate (18). When confronted with such information, the military becomes defensive and moves slowly, if at all. There have been [illegible] made to humanize the system, but [illegible] change with the leadership or may become [illegible] in the morass of the bureaucracy.

I am pessimistic about change, but this [illegible] done at an administrative level to help [illegible] family. Obviously, at this point the autocratic [illegible] of the system will probably not change [illegible] will continue to be tightly joined with the [illegible] the dismay of their families. Educating them [illegible] to what to expect from the system and from [illegible] early detection and referral of problems [illegible] classes, confidentiality of records, stability [illegible] duty, and reintegrating family sessions when [illegible] returns from an isolated tour would all [illegible].

The military has certainly had precedents [illegible] ideas; it has race relations sessions, civilian [illegible] mittees, and drug and alcohol abuse programs. [illegible] programs like these would not only help [illegible] many of the sources of family pathology [illegible] good long-run economic sense for the military.

Developmental Issues in the Psychiatric Hospitalization of Children

BY IRVING N. BERLIN, M.D.

Rather than becoming repositories for the community's seriously disturbed children, children's psychiatric hospitals need to develop milieu programs that involve trained child care staff and developmentally oriented child mental health professionals. Treatment programs should address the developmental needs and abilities of the various age groups and the particular developmental deficits reflected in their psychopathologies and should include a variety of treatment elements.

MANY CHILDREN and young adolescents are hospitalized for brief or extended periods because the severity of their illness makes it difficult for community agencies or the children's parents to contain them at home. The most frequent cause of hospitalization is psychotic withdrawn or aggressive hostile behavior that is not amenable to any other community resource. In many instances, hospital care itself provides little therapeutic intervention; however, it removes the child from the community, reducing stress on parents, schools, etc., and provides chemical and physical restraints for the child's difficult behavior.

A small percentage of youngsters are hospitalized because they are actually dangerous to themselves or others. Many preadolescents and adolescents who attempt suicide are hospitalized because a period of hospital evaluation is necessary, and, rarely, youngsters are so hostile and assaultive without apparent cause that the hospital is the only place for them. Children who have committed murder or arson need to be studied in the hospital.

Another reason for psychiatric hospitalization is a serious psychosomatic disorder such as anorexia nervosa. Often psychiatric hospitalization of youngsters with these disorders is no more effective than previous hospitalization in medical or pediatric services because critical developmental and intrafamilial data are not obtained, analyzed, and used to provide a new approach to the illness (1, 2).

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Berlin is Professor of Psychiatry and Pediatrics and Vice-Chairman, Department of Psychiatry, University of California, Davis. Address reprint requests to him at Sacramento Medical Center, 2315 Stockton Boulevard, Sacramento, Calif. 95817.

TREATMENT OF SERIOUSLY DISTURBED CHILDREN

Many psychiatric hospitals are not staffed by developmentally trained child mental health professionals. It is still rare for a mental hospital that treats children to have a well-trained child psychiatrist, child psychiatric nurse, social worker, occupational therapist, or child psychologist. The staff is rarely trained in either child development or the design of milieu programs as part of treatment. Therefore, sedation, antipsychotic drugs, isolation, and inactivity are often used, in addition to a haphazardly designed school program. In a few months the ward staff are conditioned by the child's behavior to interact with the child for the purpose of reducing disturbing behavior. Looking beyond behavior to try to understand its antecedents and causes is difficult with untrained staff. Examination of staff participation in precipitating disturbed behavior and finding methods of helping staff are unlikely on a busy, understaffed ward (3–5).

A few hospitals have used various forms of behavior modification programs to help with behavior problems. At first the reward system for positive behavior seems encouraging, but over time, unless specific target behaviors and specific contingencies to be reinforced are selected and changed as the child progresses, this potentially useful method loses its hold as the novelty wears off and no precise, continued use is implemented.

The patient who is very difficult to manage can now be dealt with by chemical restraints (6, 7). Children who appear less "crazy" but whose behavior is assaultive and destructive, often with histories of antisocial behavior coupled with brain dysfunction early in life, may be more difficult to treat with drugs and may require more individual care even though they are usually isolated (8, 9). The very withdrawn children receive little stimulation from ward personnel. It appears that in many inpatient children's settings the program is designed for staff comfort, since the strategies and techniques to promote patient improvement may not be very well defined (10–13).

MILIEU THERAPY FOR HOSPITAL CARE OF CHILDREN

In the last decade, the milieu program has become a very important part of the hospital care of children (14, 15). A milieu program involves all of the child care staff and specialists in child psychiatric nursing, a teacher, an occupational therapist, a physical therapist, child therapists (any of the mental health disciplines with special training), and a child psychiatrist (16). They plan each day's activities, which are geared to the developmental needs and abilities of particular age groups of children who have particular developmental deficits in cognitive, sensory-motor, social, or interpersonal areas that are reflected in their psychopathology. Precise developmental needs of specific children should be assessed and addressed in the program (17). One of the critical issues in the milieu program is that the program is paced to provide a variety of treatment elements without any great gaps of time that leave the child isolated and with time for self-absorption and psychotic thinking and behavior. The pacing of the milieu program is critical; program elements that require concentration, such as school or occupational therapy exercises (each of which is geared to the child's developmental level and his or her need to succeed at the next developmental level) are alternated with large-muscle activities such as dance therapy or other physical activities. These activities use the range of sensory-motor modalities and are geared to the child's developmental needs for acquiring small and large motor skills. Learning requires the same developmental planning. Such pacing and alternation of program elements throughout the day insures the child's psychological attention and involvement in each of the scheduled activities. Thus, play therapy on an individual basis should not follow a large-muscle exercise that leaves the child tired and excited and not able to become involved with the therapist (18).

Conversely, group activities may be so planned as to move from large-muscle activities in which the group is involved in cooperative building or cooperative design of a large mural, for instance, to more sedentary talking about feelings or role-modeling, and, later, to playing out of feelings by the child. The milieu efforts are designed not only to help the child with developmental deficits but to enhance his or her new and emerging capacities and promote a sense of mastery in each of the activities in which he or she is involved (19–21).

A milieu program must begin with attention to the elements of self-care, with particular attention to helping with grooming, which may alter the child's self-concept. Thus, the simple tasks of making their beds and becoming responsible for their hygiene, grooming, and the care of their rooms, which are rewarded by special persons in the milieu, are opportunities to help youngsters learn that they are capable of doing things for themselves.

If used and monitored precisely, behavior modification programs, or token reward program[illegible] effectively in many of the elements of [illegible] help deal with a child's emotional and be[illegible] lems. The use of a variety of group the[illegible] ties as well as individual therapy is cr[illegible] ment in the child.

Role of Individual Relationships

The relationship of the child to an in[illegible] pist develops as they work together tw[illegible] week. The relationship helps the child t[illegible] verbalize the feelings that often under[illegible] therapist does not respond to the beh[illegible] adults have, i.e., with retaliation or w[illegible]

The therapist can use the relationship[illegible] ually a shift from assaultive or self-des[illegible] ior to pounding pegboard tools, hitting [illegible] etc. The child's increased capacity to e[illegible] sion without hurting or destroying in[illegible] has begun to learn to express feelings [illegible] As a result of not eliciting retaliatory [illegible] therapist or other adults, the child is [illegible] first time, able to understand his or he[illegible] dent feelings that bring about the ass[illegible] structive behavior. He or she gradually [illegible] them out through the use of fantasy [illegible] (18, 20, 22).

Use of Restraint

Nonpunitive restraint provides the ci[illegible] ence with an adult over a period of time[illegible] child to become attuned to the mus[illegible] which are antecedent to the discharge [illegible] tile, assaultive behavior. From non[illegible] straint, the child discovers that he or s[illegible] able to relax muscularly and to cont[illegible] and relaxation of his or her muscles. [illegible] child to use verbal cues to let the thera[illegible] milieu personnel, know that hostile [illegible] are emerging so that they can be transfe[illegible] destructive angry expression with sub[illegible] jects. Such continued efforts can lead t[illegible] of precipitating feelings and thoughts w[illegible] wise suddenly discharged in assaultive [illegible] havior (12, 18, 23, 24).

Occupational and Physical Therapy

The importance of developmentally [illegible] pational and physical therapy progra[illegible] care cannot be underestimated. A good [illegible] py program is geared toward helping c[illegible] their mastery over their bodies and th[illegible] The increased capacity to use thei[illegible] fectively, to become better coordinated [illegible] and to use their large muscles for run[illegible] and throwing brings a great deal of sat[illegible] pleasure is similar to the gradual, develo[illegible] tuned mastery over academic skills i[illegible]

sense of satisfaction comes not just from the praise of the adult but also from the child's sense of acquisition of skills. The capacity to use these skills in the milieu occurs frequently; thus, each interaction can reflect a new level of competency and a higher level of pleasurable exchange with adults (18, 20, 25, 26).

The occupational therapy program is critical. Since the skills of the occupational therapist in developmental diagnosis of perceptual motor functioning are often highly refined, such a therapist can give a very clear evaluation of each child's perceptual motor functioning and some of his or her cognitive areas. The occupational therapy tasks can be clearly designed to facilitate the next stages in perceptual-motor development. In addition, the use of textures and colors enhances the sensory capacities of the child considerably and enlarges his or her horizons in both sensory and motor areas. The fact that many of the projects in occupational therapy produce tangible results—e.g., clay figures or drawings or the products of weaving, woodwork, etc.—is extremely important to the child's sense of accomplishment (12, 18, 22, 26, 27).

ESSENTIALS OF A DEVELOPMENTAL PROGRAM

The effectiveness of such a program depends on the clarity with which it is applied to the developmental state of the child. That is, in each developmental area the program must not demand more of the child than the child is capable of developmentally. On the other hand, it must not be geared to a level where the child is already successful, lest he or she be bored by the activity.

The educational program is a critical element of all milieu therapy. Such a program depends on a thorough, developmentally oriented educational evaluation that clearly defines the cognitive areas in which the child needs help as well as the areas of the child's successes. Areas of academic achievement can be the entree to areas in which the child needs to acquire competence (18, 25, 26, 28–32).

Group Therapy Programs

Group therapy programs must be geared to the developmental and actual age of the child. Activity groups are most effective for young children because they are learning social skills and developing coping capacities for play with a variety of age-mates. Children are involved in a variety of activities that include first those of parallel play and, later, planned activities of collaboration and competition which provide opportunities for interaction with other children. The exploration of feelings first noted and verbalized by adults leads to greater expression of angry or depressed feelings, and, as collaboration in projects occurs, increased social competence develops (16).

With the older child, the activity programs may be more sophisticated in that they may be collaborative projects which lend themselves to the expression of feelings. For example, the painting of murals may have various subjective meanings to each child as he or she depicts a family, family outings, and various other activities, as well as pictures of the child in school and in various phases of living. In such an activity in one milieu setting, murals that described "the way I get in trouble" produced in painting some of the most vivid and meaningful expressions of feelings, which provided subject matter for many discussions (6, 11, 26, 33–35).

Work with Adolescents

Whereas most younger and older adolescents will not talk freely about their own problems, they will, in the course of learning about child development and actually working with younger children in the hospital or nearby day care or mental retardation programs, begin to talk about parenting. As they talk about the problems they see in younger children, they can be helped to speculate about how these problems may result from certain parent-child interactions. Later they may reflect about similar situations in their own home and how they may have been affected.

We have found that dramatic play initiated by talented group therapists is one way of getting young adolescents to play out their feelings about some of their problems. Usually they are asked to write a scenario about the problems of another child and play those out, rather than their own problems, as a basis for discussion.

It must also be stressed that individual psychotherapy with adolescents provides an opportunity for them to form a relationship with one person over time. Such a relationship may become a critical factor in the socialization process, in the reduction of conflict, and in the move toward egosynthesis (12, 18, 23, 24, 28, 33).

Developmental Orientation in Individual Therapy

Individual therapy must be developmentally oriented and include, especially, a developmental diagnosis of ego functioning. It is necessary to understand the psychopathology of the child and the deficits in nurturance that the child has already experienced. The child's specific problems in interacting with meaningful adults must be understood so the therapeutic contacts can be restitutive. Although interpretive psychotherapy may not occur, what may develop is a relationship that permits the child to identify with an adult who behaves therapeutically toward him or her. The adolescent finds an adult who is willing to understand his or her behavior and to help look at that behavior in the context of the immediate relationship. The goal with children and adolescents is to help them alter their previous modes of relating to adults and peers, which can be noted in interactions with other staff members and fellow patients. It becomes clear that unless such interpersonal relationships are altered, the child will never be able to relate meaningfully to other human beings. Thus, all relationships may remain sterile and manipulative without warmth or intimacy. For

more behaviorally disorganized children, as with other disturbed children, the intensity of the one-to-one interpersonal relationship provides a vehicle for focusing on specific conflicts, which are beginning to be reduced in the milieu therapy program, and working through them in the context of play, mutual activities, and talking, as well as in collaborative work with parents.

Collaborative Work with Parents

Most inpatient settings do not include parents in therapeutic work. Unless parents are involved in some collaborative efforts the inpatient treatment may not be effective in returning the child to the community and home. The work of Szurek and Johnson (4, 18, 26, 41) and Schopler and Reichler (36) indicated that parents' involvement is critical to the improvement of very disturbed children (37, 38). I have observed that it is possible to elicit collaboration with even the most disturbed parents on behalf of the child. Members of the treatment team must be willing to visit the home, to see the child in his or her natural habitat, and to help the parents with those behaviors which make living with the child difficult. Gradually, parents who are helped to understand and to work on family problems will learn to manage the behavior of the child at home and make it likely that day hospital or outpatient treatment will become possible.

In my experience, parents' attendance and participation in the inpatient setting several times a week is important. Parents may work first with other children who have similar problems but with whom they do not have mutual problematic emotional involvement. Parents find they can be effective, then gradually learn how to work with their own child. We have used videotape and a "bug in the ear," an electronic hearing aid that permits the treatment team to tell the parent what kinds of interactions are likely to be most effective with the child during a particular interaction or specific project. All of these methods have been extremely helpful in collaborative work with parents. It has been my experience that one does not leave the parent and child alone simply to visit. The staff is most helpful to both the child and parent if the parent is engaged with the child in a specific cognitive or sensorymotor learning task, especially using games. These tasks can then be broken down into the elements necessary for effective performance and facilitated by example and by helping the parent learn what kinds of behavior on their part seem to encourage the child to perform a task or learn more effectively.

As parents learn to work with their children more effectively in the hospital setting, they also become better able to deal with them more effectively when they take them home. It is critical for fathers as well as mothers to be involved in such a program. Fathers who cannot come during the day are encouraged to come in the early or middle of the evening to participate in evening programs and work with their children at specific projects.

IMPLICATIONS OF DEVELOPMENTAL ASSESSMENT

It is almost impossible to make a pro[illegible] ment and do any outcome studies if the [illegible] tion has not been done developmentall[illegible] cognitive, social inter- and intrapersonal[illegible] motor areas have been evaluated, the [illegible] data help one to make a better psychop[illegible] agnosis (8, 21, 26, 30, 31, 35, 39, 40). [illegible] one can make prognostic statements fo[illegible] child. One can then develop the next st[illegible] gram that should help the child's total [illegible] Statements about prognosis, treatmen[illegible] possible, treatment outcomes within a t[illegible] mit one to evaluate the evaluation proce[illegible] to refine these steps with each new pa[illegible] comes possible to evaluate particula[illegible] milieu program with regard to a partic[illegible] velopment to determine which parts o[illegible] seem to be most effective in helping t[illegible] program can also be evaluated in the co[illegible] staff and settings are best able to fa[illegible] development. Individual treatment goa[illegible] assessed and evaluated (13).

The critical issues in a developmen[illegible] the spelling out of the incremental st[illegible] each developmental area to help the c[illegible] now have sufficient information and c[illegible] opment to attempt such a developm[illegible] and therapeutic approach. Thus, both [illegible] outcome can be evaluated more clear[illegible] very seriously disturbed children, and [illegible] ually learn to refine our assessment [illegible] treatment skills.

SUMMARY AND CONCLUSIONS

As inpatient settings become more [illegible] velopmental efforts, they can more clea[illegible] areas of expertise and their capacity fo[illegible] dren, rather than becoming repositori[illegible] munity's difficult children, staffed by i[illegible] feel hopeless about understanding th[illegible] culties and helping them therapeutically[illegible] velopmental approach one must hire o[illegible] can train others in developmental dia[illegible] ment. Where this approach is used [illegible] slowly, it is a potentially effective wa[illegible] seriously disturbed children.

OPINION AND COMMENT

The American Psychiatric Association and the Food and Drug Administration: An Analysis and Proposal for Action

BY RICHARD DORSEY, M.D., M.B.A.

The relationship between medicine and society is currently undergoing substantial change. While the Food and Drug Administration has no legal authority over the practicing physician, its decisions already influence medical practice. The Drug Regulation Reform Act of 1978, if passed in its present form, would grant FDA broad new powers over patient care and clinical research. In order to retain a high degree of control of its future and activities, the American Psychiatric Association must develop an effective mechanism for meeting this challenge and for serving the interests of its members and their patients. Dr. Alexander M. Schmidt comments on the author's presentation.

THE AMERICAN Psychiatric Association (APA) has recently taken several significant steps toward more effectively representing psychiatrists and their patients. Government regulation of the prescribing of medication, which is likely to be the next focus for attempted control over medical practice, was addressed by Dr. Daniel X. Freedman's testimony on H.R. 12,391 (1).

In addition, *Psychiatric News* obtained and published excerpts from a transcript of the Psychopharmacological Agents Advisory Committee review of labeling for lithium carbonate (2), which, one hopes, presages direct coverage of committee m[illegible] ly all of which are now open to the p[illegible] these steps, there is a critical need for a[illegible] tation of our views on the availability, a[illegible] motion, and proper use of psychotropic [illegible] major problem areas offer immediate cl[illegible]

Dr. Dorsey is Director of Psychopharmacology, Emerson A. North Hospital, Cincinnati, Ohio. He is also a consultant to the American Psychiatric Association Committee on Peer Review and a medical consultant to a major pharmaceutical company. Dr. Dorsey's address is 7913 Euclid Ave., Cincinnati, Ohio 45243.

THE FDA'S PROBLEMS

Role

As with many regulatory agencies, the [illegible] of the Food and Drug Administration (F[illegible] what ambiguous. This leads to internal [illegible] decision making and external criticism [illegible] constituencies, each of which believes [illegible] priorities should be the same as its own. [illegible] protection" sounds clear until one ques[illegible] consumers are to be protected from drug[illegible] Many healthy Washington health officia[illegible] cates lean toward the former. However, [illegible] controversy suggests that the general pu[illegible] larly those individuals suffering from ser[illegible] are more concerned with the availability [illegible] than with the documentation of safety a[illegible] the satisfaction of "guardians of the co[illegible] est" (3, 4).

In addition, FDA deals with broad [illegible] questions in deciding on the overall risks [illegible] of the availability or promotion of part[illegible] However, the physician who prescribes [illegible] whose marketing FDA must approve treat[illegible] dividually, rather than in the aggregate. [illegible] may seem an inordinate risk for a large pop[illegible]

Papers in the Opinion and Comment section present pro and con statements and discussion of issue[illegible] psychiatry.

be highly appropriate for a particular individual or subgroup. Further, practitioners, academicians, and medical administrators may differ in their assessment of risk-benefit ratios even for identified populations or individual patients.

Finally, FDA is not a monolithic entity. Some staff members advocate expansion beyond the regulation of the pharmaceutical industry into the provision of drug information to patients (through the "patient package insert" [5]), greater control of drug use as well as drug labeling, and greater agency discretion in evaluating the relative merits of drugs in a particular class. Other FDA personnel feel current agency responsibilities provide more than sufficient challenge and workload and would prefer to concentrate on improving their capacity to deal with the problems at hand.

Complexity of Decisions

Few physicians outside industry and government appreciate the number and complexity of considerations involved in decisions regarding drug regulation. The scientific issues are difficult enough, since data are often incomplete and commonly subject to varying interpretations even by unbiased experts. In addition, the law requires the application of different standards in decision making for different purposes, being most stringent in requirements for the approval of new drugs or new indications and most lax (frequently to the point of scientific invalidity) with respect to adverse effects,

Although good science constitutes the beginning of the drug regulatory process, it is by no means the end. All decisions must be made within the FDA administrative framework; this fact alone imposes a certain amount of delay and costs both the government and the manufacturer time and money. Beyond this point, FDA's decisions are subject to judicial and political review, both of which consider scientific evidence among a number of factors. However, in neither instance do scientific and clinical considerations assume the centrality to which physicians are accustomed in patient care and professional journals.

THE AGENCY'S STAFF

In part because of real recruiting difficulties and in part because of conflicts over agency goals and performance, the quality of FDA staff has frequently been criticized. For example, Senator Edward Kennedy observed in a speech at Tulane University in November 1975,

> It is a fact of life that only top-notch scientists can correctly judge the scientific work of other scientists. By and large, although there are many able scientists in FDA, it has failed to attract and keep the top level scientific talent that it needs.
>
> The consequences are serious. Too often, FDA yields to the temptation to use precaution and delay as substitutes for expertise and scientific judgment. Again, the public pays the price. Badly needed drugs are delayed from joining the fight against disease—not because they are dangerous; not because they are unsafe; but because of the FDA's well-deserved inferiority complex about its scientific judgment.

While this statement reflects some political hyperbole, it is true that the FDA Division of Neuropharmacological Drug Products has not been headed by a psychiatrist since 1974, in contrast to the National Institute of Mental Health, whose staff includes a number of world-famous psychopharmacologists. During most of 1976 the directorship of the division remained vacant, and a neurologist currently serves as the director.

The nature of regulation, with its emphasis on reviewing the work of others, adversary relationship with various groups, and vulnerability to political and legal considerations, rarely appeals to outstanding scientists. The intellectual freedom, professional prestige, and insulation from worldly pressures characteristic of academia or the National Institutes of Health constitute incomparably more agreeable working conditions for most creative researchers.

However, scientific creativity may be less important in the discharge of current FDA responsibilities than such attributes as fairness, diligence, appreciation of the regulatory procedure, and the ability to live with persistent criticism. The staff of the Neuropharmacology Division are generally experienced, fair, and familiar with scientific and regulatory issues. In recent years they have made considerable progress toward facilitating the review of submissions and clarifying the scientific issues presented to their advisory committees.

In the current political climate only scientists of high professional stature, adventuresome temperament, and assured alternative employment are likely to take the calculated risks involved in substantially shortening the time required to review new drugs. Without such individuals in FDA, the outlook is for continued refinement of the basic approach of cautious fairness. Such an approach may be adequate, although not optimal, to discharge present agency responsibilities. However, it will fall far short of the pace and flexibility required if FDA's authority is expanded in ways now under active consideration.

ADVISORY COMMITTEES

The approach frequently proposed to strengthen FDA's internal scientific talent is reliance on advisory committees composed of leading outside experts, usually from academia or the National Institutes of Health. The immediate problem is that agency staff are still legally responsible for all decisions, even those made on the advice of outside consultants. Thus the conservative bias of the system remains, although it is leavened by external views and support.

Advisors (some of whom are nonphysicians) are selected on the basis of their expertise in research, rather than their skill as clinicians or their knowledge of usual medical practice throughout the country. Accordingly, they must sometimes venture beyond their depth in deciding, often in an atmosphere of apparent political urgency, what labeling changes to recommend to appropriately inform and influence the practicing physician. For guidance on regulatory and administrative affairs, the advisors must generally defer to FDA staff, some of whom may also have limited clinical knowledge and experience.

Another major problem for advisory committees is time. Most advisors have numerous other commitments and are not able or expected to devote the time necessary to achieve mastery of the regulatory issues to be resolved or to work continuously with FDA to assure that satisfactory decisions are reached and implemented.

THE PHARMACEUTICAL INDUSTRY

Unfortunately, many of FDA's staffing problems are not unique to government but appear in the pharmaceutical industry as well. The need for initiative and scientific creativity is probably greater in industry than at FDA, since drug companies generally conceive, finance, and monitor the research studies forming the basis of submission that FDA reviews.

Relatively few of industry's psychopharmacology research programs are directed by psychiatrists, and a number of corporations with significant research commitments to the central nervous system area have no psychiatrists at all on their research staffs. Assignment of monitoring responsibility for psychotropic drug trials to physicians who lack formal psychiatric training often leads to limitations in study design and management, difficulties in communication between industry physicians and investigators, and the estrangement of industry from academic psychiatry. This reality reinforces FDA's emphasis on documentation and its skeptical attitude toward industry submissions. The net result is the expenditure on both sides of substantial amounts of time, energy, and resources that could otherwise be devoted to more socially productive research. It also means that the introduction of effective new compounds may be delayed or even abandoned because they do not meet the high U.S. standard of scientific evidence.

ISSUES OF DRUG REGULATION

Several major issues surrounding drug regulation require clarification. Despite court decisions, professional testimony, scientific publications, and statements by FDA commissioners, widespread misunderstanding on these points still unnecessarily clouds public debate and medical practice.

The FDA's Authority

The FDA's control over the pharm[illegible]try derives from the federal govern[illegible]tional power to regulate interstate co[illegible] agency currently has no statutory a[illegible] practicing physician (6, 7). Although [illegible]gally unfettered by FDA in prescribi[illegible] his or her individual patients, FDA h[illegible] direct influence over the practice of [illegible]

First, drug labeling, particularly as [illegible] *Physicians' Desk Reference* (8), cons[illegible] source of prescribing information. [illegible] which must be approved by FDA, a[illegible] pharmaceutical companies may say in t[illegible] and detailing, with the goal of assuring [illegible] sonable scientific accuracy and fairness [illegible] promotional communications.

Unfortunately, many physician[illegible] estimate the scientific validity of [illegible] feel obliged to prescribe in accordan[illegible] mendations in the package insert. [illegible] courts may mistake labeling for a def[illegible] treatise rather than a regulatory docu[illegible] undue weight in defining a standard of [illegible] fessional liability cases. Thus even [illegible] has had considerable experience wi[illegible] inclined to conform to the recomm[illegible] package insert in prescribing rather [illegible] her own professional judgment.

Finally, many public programs h[illegible] beling to directly constrain presc[illegible] reimbursement to drugs given for [illegible] dications." For example, a military d[illegible] ceive methylphenidate at no charge f[illegible] of childhood hyperkinesis, but not [illegible] the effects of tricyclic antidepressa[illegible] Similarly, the question of Medicare [illegible] treatment of multiple sclerosis with A[illegible] the absence of agency "approval" c[illegible] was formally raised at a recent m[illegible] Neurological Drugs Advisory Commi[illegible] all, some state mental health commis[illegible] their own initiative or under court o[illegible] their staff physicians to prescribe [illegible] doses of psychotropic drugs despite [illegible] are often inadequate, particularly [illegible] in public hospitals.

Labeling

Drug labeling constitutes "all labe[illegible] ten, printed, or graphic matter (1) u[illegible] any of its containers or wrappers, or [illegible] such article" (10); this definition has [illegible] judicial and regulatory decisions to re[illegible] tising and detailing. As such, it cons[illegible] cense to promote" and a constraint [illegible] said by the manufacturer. On the the[illegible] turers will tend to overstate the benefi[illegible] the risks of their products, the regula[illegible]

intentionally biased in a strongly conservative direction in the hope that on balance a reasonably accurate presentation will emerge.

Changes in labeling to expand indications or increase dosage must generally be initiated by the manufacturer's submitting a request and supporting documentation. Since such submissions are quite expensive, particularly if original research is required, manufacturers are reluctant to commit the necessary time and money unless a commercial benefit is anticipated. For example, labeled dosage ceilings for most tricyclic antidepressant and antipsychotic drugs are inappropriately low in light of current information, not because psychiatrists, manufacturers, or the FDA do not know any better, but because there is no real incentive for manufacturers or the FDA to change the status quo.

Thus labeling is at least as often obsolescent as authoritative. For example, labeling for diazepam (Valium) included a warning against its use with epileptic patients at a time when it was generally regarded as the drug of choice for status epilepticus. The value of imipramine hydrochloride (Trofranil) for childhood enuresis was recognized for nearly a decade before the labeling was changed. With the exception of haloperidol (Haldol), the maximum recommended doses for most of the antipsychotic drugs are far below those generally recognized as appropriate for significant numbers of patients. Labeling for most tricyclic antidepressants contains no information regarding the correlation between plasma levels and clinical response or the need for daily doses well above 300 mg for selected patients who are rapid metabolizers of these drugs (11).

Introduction of New Drugs

Lasagna and Wardell have been among the leaders in stressing the decline in the introduction of new chemical entities since the Food, Drug, and Cosmetic Act was amended in 1962 to require proof of efficacy as well as of safety. They have also pointed out the delay in the introduction of new drugs to the U.S. market compared with Western European countries having a high standard of medical practice; they coined the term "drug lag" for this phenomenon (12, 13).

Not surprisingly, one result of the stringent U.S. regulations has been a shift of basic drug research to other countries by large, multinational pharmaceutical companies (14). Such a development threatens American leadership in medicine and science, reduces the opportunity to study promising new compounds in their early phases, and weakens this country's basic research structure by exporting jobs and contracts.

NEW LEGISLATION

Background

The Drug Regulation Reform Act of 1978 (S. 2755, H.R. 11611), which is currently moving through Congress with the support of the Administration and key legislative leaders, will provide FDA with breathtaking new powers over the medical profession. Despite the fact that a number of the Act's major provisions, including those summarized below, will be intensely objectionable to most psychiatrists, APA has not yet taken a position on this legislation, thus leaving the burden of opposition to AMA and a few individual physicians.

Approval of New Drugs

The Administration has, in essence, taken the position that although there is no "drug lag," new legislation is needed to eliminate it. The basic rationale for the Act derives from its sponsors' contention that it will accelerate the development and introduction of new drugs. However, AMA, academic pharmacologists, the pharmaceutical industry, and even FDA's own career staff have testified that the actual result is more likely to be further delay.

Medical Practice

Under certain circumstances the offices of all physicians prescribing drugs released into "controlled distribution" would be transformed into "regulated premises," which FDA inspectors would be authorized to enter without a warrant on the suspicion that the physician might be prescribing these drugs in ways not approved by FDA. Inspectors would have wide discretion to inspect and copy the medical records of individual patients. FDA could also issue its own subpoena to compel a physician to appear in person anywhere in the United States and to produce whatever records and documents might be demanded. Hearings on alleged prescribing violations would be conducted, not by a court but by FDA, who officials would act as prosecutor, judge, and jury, with the power to assess fines up to $10,000. Only after the issuance of a final order by the Department of Health, Education, and Welfare would the physician have the right of appeal to the courts.

Thus even the most innocent physician, acting in good faith and according to sound professional judgment, would be exposed to the wholesale violation of his or her patients' confidentiality and to the complete disruption of his or her practice or other professional work. The economic cost of productive time lost and legal fees paid will be burdensome even for large corporations; for the individual physician they will be nothing short of ruinous.

The Administration acknowledges all of these possibilities but seeks to soothe opponents by claiming that these powers would be used only in exceptional circumstances. However, nothing in the history of FDA and of its parent agency, the Department of Health, Education, and Welfare, provides a rational basis for reliance on the self-restraint of government officials.

Patient Information

Despite the limited scientific evidence on the effects

of providing drug information to patients, the Act mandates the development of patient package inserts for most major classes of drugs and requires that the pharmacist dispense them with the prescribed medication. In most cases the physician can direct that a particular patient not receive the package insert, but as a practical matter the patients for whom this information may do more harm than good are likely to be people who will be even more upset by knowing that something is being withheld from them. Worse still, FDA will have the power to override the judgment of a physician for an individual patient and to require that *all* patients receive package inserts for certain drugs.

FDA will also have the power to require that physicians obtain written informed consent, in the precise form and manner dictated by government, as a condition of prescribing certain drugs. In addition, FDA will be able to mandate that physicians notify all patients of specific major hazards of particular drugs even if the physicians disagree with FDA's assessment of the risk, believe that notification would do individual patients more harm than good, or find that identifying and contacting large numbers of these patients would be extremely difficult and burdensome.

Research

At present FDA's authority over medical research is limited to studies sponsored by pharmaceutical companies. However, this Act would bring *all* drug research in humans under FDA control and would require prior FDA approval for the conduct of drug studies, under pain of heavy civil penalties. In addition to the obvious threat to academic freedom, this provision would have the bizarre result of requiring the most distinguished clinical investigators in the country to seek the approval of obscure FDA staffers whose principal qualification to act as arbiters of research consists of desks flanked by an American flag.

PROPOSED APA POLICY

Latitude for Physicians

In dealing with regulatory agencies generally, APA should adopt an explicit policy favoring maximum latitude for the individual physician, subject to appropriate review and controls by organized medicine and psychiatry. As applied to drug regulation, such a policy would have several specific implications.

First, APA should press for earlier availability of new drugs so that larger numbers of psychiatrists can use them and explore their role in the treatment of mental disorders. Prompt reporting of new drug uses and adverse effects in the *American Journal of Psychiatry* should be explicitly encouraged. APA should also provide vigorous public support when FDA does approve new psychotropic drugs or appropriate labeling revisions and not leave the agency to face hostile political and journalistic fire alone on these occasions.

APA should work with the American M ciation (AMA) and other medical specialty resolutely oppose any federal constraints marketed drugs by individual physicians vidual patients. Such a policy has adopted by AMA, whose House of Dele in 1975 that

> the American Medical Association contin and seek to modify any restrictive regulat ened to interfere with the exercise of a ph sional prerogatives in selecting the ther choice for his patients . . .[and] that the A Association continue to work for extensiv by practicing physicians in the review of e and development of FDA policy. (15)

APA should testify and lobby vigorous new legislation that would impose feder restrictions and should be prepared to challenging any such laws. It should AMA's example in providing formal FDA proposals published in the *Federa* nally, APA should press on the national els for the abandonment of any administ requiring physicians to prescribe in acc labeling or limiting reimbursement to d for "approved indications."

In exchange for the earlier introductio and continued broad prescribing freedo cooperate in an effective surveillanc mechanism. Lack of the former has b reason for delaying the introduction of the possibility of providing reasonable timely reports of adverse effects sho FDA's apprehensions in this regard dubious prescribing clearly does exist need to take corrective action to avoid would have a pernicious effect on the ov patient care in order to constrain poo small minority.

For both purposes, Professional St Organizations (PSROs) or other local ganizations should be advocated as mechanism. The PSRO program, to w government is already committed, was provide public accountability for m while assuring that "decisions on m made by other physicians rather thar tors or bureaucrats"(16).

Part of the quality assurance focus on prescribing, and adding a surveilla adverse effects of new or existing dru system should not be unduly difficult establishing such a system, the coope and the specialty societies might reason as in the AMA-Health, Education, and Model Screening Criteria Project (1 ment of Model Psychopharmacological teria by APA on contract to the Natio

Mental Health represents one significant step in this direction.[1]

In addition, APA should take the initiative to enhance psychiatrists' knowledge of psychopharmacology at all levels, from residency training through continuing education in practice. Increasing emphasis should be placed on the proper use of psychotropic drugs, their common interactions and adverse effects, and the appropriate assessment of therapeutic risks and benefits.

APA should also explicitly address the consumer protection issue as it relates to psychotropic drugs. Psychiatrists understand the need for proven efficacy, reasonable safety, and full disclosure of the effects of drugs, as well as the desirability of properly protecting research patients. However, many other groups emphasize these issues strongly and, on occasion, to excess (18). APA's greatest contribution to the drug regulatory dialogue may lie in emphasizing the need for greater balance between the risks of illness and the risks of treatment. The importance of preserving maximum latitude for the patient and his or her physician to select treatment on an individual basis should be stressed. Emphasis should also be placed on reviewing the substantive benefits and hazards faced by research patients, rather than on the precise composition of human research committees or the attempt to explicate and guard against every conceivable risk.

Similarly, while remaining alert to the high financial stakes involved in the pharmaceutical industry, psychiatrists should remind the public that profit in the private sector has no greater capacity to induce misrepresentation and deception than does power or ideology in the public sector. From our experience with state hospital systems and community mental health centers, we should, of all specialties, be most keenly aware that government control assures neither quality nor equity.

Finally, APA should press FDA to include a full disclosure statement on drug labeling informing the physician and other interested parties that the labeling is primarily a regulatory rather than a scientific or medical document. With particular regard to "indications," I have recommended elsewhere (19) that the following statement be included in the package insert in order to put "FDA approval" into proper perspective: "Based on evidence submitted to the Food and Drug Administration, the manufacturer has been authorized to recommend the following uses of this drug." Similarly, the "adverse effects" section should disclose that this list includes many phenomena that have been reported to occur in patients while taking the drug but for which a cause-and-effect relationship has not been established.

The AMA House of Delegates has made a similar recommendation, resolving in 1975

> that the AMA petition the FDA to adopt a standard paragraph in all package inserts to read substantially as follows: Most package inserts of necessity represent a summary of the information available about the drug upon which approval for sale was based. This should be regarded as a guide for the physician who must combine the best knowledge from all sources with individual patient considerations in deciding upon appropriate therapy. This should not be considered as a legal controlling influence over drug use by a given physician in the management of an individual patient. The package insert gives the parameters within which the pharmaceutical manufacturer may advertise or publicize this product. (15)

Benefits of Drugs

The second key element of APA policy should consist of emphasizing the proven value of drugs for the treatment of mental illness. APA also needs to assure wide dissemination of the evidence of the biochemical basis and genetic transmission of the more severe disorders (particularly schizophrenia and affective illness), of which even sophisticated laymen are often unaware, and to point out the limitations of alternative forms of treatment. Further, psychiatrists should note the additive effects of pharmacotherapy and psychotherapy for several major mental disorders (20–22) and emphasize the importance of the psychiatrist's medical knowledge in properly applying either or both modalities.

For maximum public policy appeal, APA should stress the cost-effectiveness of pharmacotherapy and its broad applicability and availability to most segments of the population. In addition, evidence of the beneficial effects of drug treatment for the more severe disorders, which are most common among the poor, elderly, and minorities, should be well-received by Congress.

APA ACTION

Commitment

The first step in addressing the above issues must be a decision by the APA Board of Trustees to pursue an aggressive policy concerning drug regulation. In essence, APA must make a commitment to work with FDA and its congressional oversight committees similar to that already undertaken to deal with insurers. The latter arrangement probably represents a good general model for APA's relationships with the financial, regulatory, and consumer groups likely to have substantial influence on the practice of psychiatry in the next decade.

To assure adequate coverage for psychiatric services under existing third-party mechanisms and under national health insurance, APA has been working for a number of years to develop good relations with government, Blue Cross and Blue Shield, and commercial insurers. Those involved have attempted to address the concerns of these groups and to educate them on

[1]These criteria will be published later this year. APA's role in developing these criteria is noted in the present context and in light of Dr. Schmidt's comments.

our view of clinical reality and public necessity. The Commission on Standards of Practice and Third-Party Payment was established to negotiate with insurers and to coordinate the work of other APA components, including the Council on Mental Health Services and the Committee on Financing Mental Health Care and the Committee on Peer Review. APA also established a field consultant program in peer review to strengthen this activity at the district branch level and to gather information about developments across the country to share with insurers and government at the national level.

Perhaps most importantly, the Association has established a clear and consistent policy of seeking parity in insurance coverage for mental illness with other medical disorders and in exchange offering equal or better accountability through peer review programs and cooperation with third parties. A similarly explicit commitment to goals for drug regulation will be required if APA is to be effective in this area.

Liaison

The Joint Commission on Government Relations and/or the Council on Research and Development should establish liaison with a number of organizations including FDA, AMA, the American College of Neuropharmacology (ACNP), and the Pharmaceutical Manufacturers' Association (PMA). With FDA we should articulate and press for the regulatory actions outlined above. With AMA and ACNP we should coordinate our positions and lobbying efforts. With PMA we should seek mutual understanding and cooperation, exchange of information, and support for mutually acceptable positions.

Representation

Current FDA regulations (23) provide

> the mechanism for nominating and selecting nonvoting members of standing technical advisory committees. In the past three years, the Commissioner has increasingly included such nonvoting members to represent consumers and industry on standing technical advisory committees. These members serve a liaison function with those whom they represent.

Because of their lack of a vote and their well-understood liaison role with a particular interest, these individuals meet the statutory requirement that "any financial interest they may have in the particular class which they represent does not constitute a disqualifying conflict of interest"(23).

The FDA Commissioner has formally noted that

> nonvoting consumer and industry liaison representatives have served on all of the OTC [over-the-counter] drug review advisory committees, the biologics review advisory committees, and the medical device classification panels, with enormous success. With rare exception, their conduct has been entirely dignified and proper, and they have made major contributions to the issues pe... these advisory committees. (23)

committee actions. In the case of any rejections of new drug applications, our representative and the Council on Research and Development should report in the *Journal* whether they believe the rejection was due to intrinsic deficiencies in the drug, shortcomings of research design or conduct by the manufacturer, or undue stringency on the part of FDA.

CONCLUSIONS

We are passing through an era in which the relationship between medicine and society is undergoing substantial change. Whether our profession will retain a high degree of control over its own destiny and activities, subject to negotiation with government and other major societal groups, or will suffer regulatory smothering and financial starvation depends in large part on how effectively we organize and negotiate over the next few years.

Pharmacotherapy has revolutionized psychiatry, shedding light on the pathophysiology of several of the major mental disorders and offering treatment of demonstrable efficacy, cost effectiveness, and wide applicability. Control over the entry of new psychotropic drugs into the U.S. market rests with the Food and Drug Administration, which also must approve the labeling for existing medications. While the agency currently has no legal authority over the practicing physician, its decisions do influence medical practice. In addition, the Drug Regulation Reform Act of 1978 would revolutionize the relationship between the federal government and the medical profession by extending FDA's authority directly into patient care and independent drug research.

Accordingly, APA must develop an effective mechanism for meeting this regulatory threat and for serving the interests of its members and their patients. The Association's commitments and programs in the insurance and peer review fields constitute the best model for such an undertaking in pharmacotherapy.

Comment

BY ALEXANDER M. SCHMIDT, M.D.

AFTER I HAD been beaten, in my turn, by the grade-school bully, my father asked me whether my two best friends and I, fighting together, could give our assailant a thrashing. I said, "Sure," whereupon my father suggested that the three of us visit the bully and quietly and politely describe in detail what would happen if he so much as laid a finger on any one of the three of us in the future. It was thus that I learned the important social principle that organized individuals working together in common purpose can do what the same people cannot do alone.

It is this principle that Dr. Dorsey is talking about; his words are as important to psychiatrists as my father's were to me, and for the same reason. Dr. Dorsey is concerned that the medical profession in general, and psychiatrists in particular, are being bullied by regulations, regulators, and Congress. More important, he clearly, concisely, and, in my view, accurately describes practical corrective measures that APA could take. Dr. Dorsey's paper is an important and worthy challenge to the APA and one that ought to be accepted.

I agree with Dr. Dorsey's analysis of the many complex and controversial issues surrounding FDA and the drug industry. He is careful to present a balanced and fair view of the problems presented by, and suffered by, FDA and its staff; and he takes note of FDA's efforts to resolve at least some of those problems. His major thesis is that FDA could use some help; and again, he is correct.

The following scenario is being repeated all too often in Washington: a scientist, somewhere in the world, in a speech, paper, or press release, presents his or her conclusion that a particular drug is a carcinogen, a teratogen, or whatever. The press picks this up, recognizes the sensational news value of the story, checks only whether the scientist actually released it, and then reports the story widely. A congressional staff member, sensing the story's sensational news value to his or her employer, arranges a hearing into the matter. At the hearing carefully selected witnesses testify to the overuse and misuse of the drug, which FDA is called upon to explain. FDA is urged strongly to do something about the problem; there is another round of sensational press repor[illegible] tually, regulations are proposed.

During my tenure as Commissioner [illegible] Drugs, this sequence of events occurred [illegible] ening regularity and with distressing resu[illegible] seldom able to defend itself very well at [illegible] ing, and it should not have had to try. C[illegible] case of misuse of drugs, it should not ev[illegible] FDA that was called to account! But [illegible] again, while violence was being done to [illegible] and often to good scientists, FDA was a[illegible] ness table.

The problem in this scenario is not the [illegible] by a scientist of data suggesting a here[illegible] pected drug danger. Any scientist is o[illegible] port his or her results. The error is tha[illegible] port and the ensuing events were usua[illegible] those who should have been paying t[illegible] tion—the professional organizations c[illegible] the proper use of the drug in question.

At times the initial report resulted i[illegible] study, the data were improperly handle[illegible] could be countered by existing data fr[illegible] ies. Usually, unless FDA already knew [illegible] they went unreported in the press o[illegible] This was in large part true because whe[illegible] hearings on important drugs were held [illegible] professional organizations were unawa[illegible] ings—or if they were aware, they did n[illegible] to monitor the hearing, let alone testify [illegible] inaccurate reports from congressiona[illegible] rected by a properly indignant public s[illegible] prestigious professional organizatio[illegible] organization insist on testifying, even [illegible] advance of a hearing. Later, when FD[illegible] sions discussed with its advisory com[illegible] in question, professional organization[illegible] rarely be in attendance or contribute.

It is important to realize that Cor[illegible] FDA's role. In the long run FDA can [illegible] less than Congress tells it to do. And [illegible] process is conducted in hearings, com[illegible] and mark-up sessions, most of which a[illegible] bad legislation results from that proce[illegible] because those who could have made it [illegible] aloof or uncaring. Thus in a real sense [illegible] ting the regulation it deserves because [illegible] the legislative process.

FDA's present role is not ambiguou[illegible]

Dr. Schmidt is former Commissioner of Food and Drugs, U.S. Food and Drug Administration. He is now Vice Chancellor for Health Services, University of Illinois at the Medical Center, 1737 West Polk St., Chicago, Ill. 60612.

0002-953X/78/0009-1057$0.35 © 1978 American Psychiatric Association

tect the public from unsafe and/or ineffective drugs. In judging whether drugs are safe and effective, FDA needs all the help it can get, and the advisory committee system now in effect is the best way for FDA to get that help. The advisory committees function for the most part in open session, so that interested parties can know what is happening and can influence the proceedings. The proper function of the advisory committees is to answer *scientific* questions, sharply put by the agency; FDA must, and properly should, handle the legal and political questions. It is when the scientific basis of FDA's actions is shaky that the political pressures can become determinative. But even when scientific proof is lacking, a consensus of unbiased and expert scientists can suffice to protect against foolish or even dangerous interpretations of scientific matters by bureaucrats, politicians, and judges.

I can criticize Dr. Dorsey only for passing lightly over some of the problems owned by medicine and psychiatry. For example, he favors "maximum latitude for the individual physician" in prescribing drugs, "subject to appropriate review and controls by . . . medicine and psychiatry." That is all right, but who is going to review and control the prescribing habits of individual physicians—APA?

Dr. Dorsey calls for better reporting of adverse drug reactions. As malpractice insurance rates and court settlements have risen, the reporting of drug misadventures has fallen. No one has yet been able to devise a satisfactory reporting system for adverse drug reactions. If the earlier release of drugs is to depend on practicing physicians' more accurate and timely reporting of adverse drug reactions, then the drug approval process will not accelerate significantly.

However, these minor criticisms do not detract from the need for APA and its members—indeed, all professional associations and their members—to heed Dr. Dorsey's call. Doing what he suggests is the *only* way, short of dissolving Congress, that we can have a beneficial impact on a legislative process that results in oppressive regulatory schemes.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1979. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or other work, including audiovisual presentations (films, etc.), submitted to or presented at any professional meeting or published during the period from November 31, 1977, to December 1, 1978. A plaque and an honorarium of $500 will be presented to the award recipient at the Convocation of Fellows at the 1979 APA annual meeting in Chicago, Ill. Please note that the award recipient is now required to give a lecture at the annual meeting.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Carl P. Malmquist, M.D., Chairman, Guttmacher Award Board, 1700 18th Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is December 1, 1978, and any entry to be considered must be in Washington by that date.

EDITORIAL

Lithium: Developments in Basic and Clinical Research

LITHIUM IS THE OLDEST of our modern psychotropic drugs. Its efficac treatment of mania was discovered by Cade in 1949, investigated more th by Schou and others in the 1950s and 1960s, and finally accepted for clinic by the Food and Drug Administration in 1970. Like most psychotropic was discovered accidentally or from the wrong hypothesis. Cade's hypothe uric acid was involved in the pathogenesis of mania led him to use lithium blood and tissue levels of this metabolite because lithium urate is sol hence could be excreted. He quickly disproved his own hypothesis, but h ical results about lithium's therapeutic efficacy have been widely co Today, most would agree that lithium is the most specific and, for the c for which it is indicated, the most effective psychotropic drug available. used with the most precision because serum levels are easy to obtain an used to keep the patient in the therapeutic range, avoiding toxic levels. W is done, more than 75% of patients with acute mania respond within 2 Lithium is prophylactic in most patients with bipolar II depression, mi both the manic and depressive phases of the illness. Its role in unipolar d is still uncertain.

There have been reports of lithium's effectiveness in conditions as d hyperactivity in children, premenstrual tension, schizophrenic illness, holism, and in eliminating the euphoria of drugs of abuse, but these stu yet to be done with the rigor and the large populations that have characte work on affective illness. Should they turn out to be positive, we wil reconsider whether there are components of affective illness in those co which clinically have not been considered to have them, or whether the mode of action of lithium transcends specific clinical diagnosis by alter fundamental property like neuronal membrane permeability to endoge ions and thus altering the uptake and release of those organic molecu influx and efflux are associated with ionic flow.

The mechanism of action of the lithium ion (Li^+) is by no means clear it seems certain that the ratio of intracellular to extracellular Li^+ is cruc this ratio is crucial for the endogenous cations sodium and potassium. much research on affective illness implicates disorders of neurotransm tion, a good deal of attention has been paid to the effect of Li^+ on these. decreased release and increased reuptake of norepinephrine, which i ent with its antimanic effects. However, it is less clear how the antidep and prophylactic effects in bipolar patients are mediated. Li^+ also alte lease, uptake, and synthesis of serotonin. It alters the transport of gluco acids, and other cations across cell membranes. Many synthesis and rel tions of the neuron are calcium-dependent and are modulated by magnes competes with these ions to alter these functions. The Li^+ ion at low co tions alters adenyl cyclase activity and cyclic AMP levels, which are bel

0002-953X/78/0009-1059$0.40 © 1978 American Psychiatric Association

be components of neurotransmitter receptors. These multiple actions of Li^+ are perhaps to be expected because the endogenous cations like Na^+, K^+, Ca^{++}, and Mg^{++} also have multiple actions. Research on the mechanism of action of lithium at this level is in the province of the basic scientist and will undoubtedly be unravelled with time.

Of greater significance to the clinician is the search for even more effective methods for using lithium therapeutically, for more precisely defining the conditions in which it is useful, and for understanding the biological defects of those illnesses in which it is effective. The three papers in this issue of the *Journal* from the laboratories of prominent investigators at the University of Pennsylvania, Columbia University, and the University of Chicago address these questions.

Since intracellular accumulation of Li^+ is clearly essential for its action and is not measured by plasma levels, several years ago the Pennsylvania group suggested that the erythrocyte concentration and the calculated ratio of RBC to plasma lithium (Li^+ ratio) might also be useful. Even more useful would be the intraneuronal Li^+ concentration, but this is not feasible in clinical research. In their early work, they found that the ratio (which is always less than 1 and usually averages about 0.4) showed considerable intersubject variance but is quite constant for any subject over time. This early work suggested that the Li^+ ratio was lower in lithium nonresponders than in responders, that it separated unipolar from bipolar depressives, and that it might be under genetic control. These observations stimulated controversy and considerable research in many laboratories. Typically, the questions asked are basic, clinical, or at the interface. At the basic level the questions relate to the mechanisms by which Li^+ enters the cell, leaves the cell, and by which an equilibrium is established between cell and plasma. At the clinical level, there are the questions of the significance of these cellular mechanisms for the pathogenesis of affective disorder and for the prediction of clinical response. At the interface, there is the question of whether in vitro tests can be developed that would offer better predictors than are now available, as well as more sensitive indications of appropriate dosage.

The Chicago group addresses the basic science problem and elegantly summarizes the evidence for the mechanisms by which an equilibrium is established between intracellular and extracellular Li^+. Li^+ enters the RBC by three mechanisms which can be chemically dissected in vitro. It moves passively from higher concentrations to lower, i.e., from the plasma to the cell. It uses the same energy-consuming Na^+-K^+ dependent ATPase pump that actively transports these ions in directions opposite to their concentrations, i.e., K^+ into the cell and Na^+ from the cell to the extracellular space, and it uses a Na^+-Na^+ exchange pathway that alters membrane permeability to sodium and thereby facilitates a stoichiometric exchange diffusion. The first pathway is chemically insensitive, the second is inhibited by ouabain, and the third by phloretin. Li^+ leaves the RBC by passive diffusion and also by a phloretin-sensitive Li^+-Na^+ facilitated exchange diffusion pathway. The steady-state distribution between RBC and plasma reflects a dynamic balance between the influx via the chemically insensitive diffusion pathway from the high plasma concentration to the lower RBC concentration and the efflux via the Li^+-Na^+ counterflow system which keeps the intracellular concentration of these ions below the extracellular concentration.

Interestingly, these researchers have found a manic-depressive patient in whom the phloretin-sensitive pathway is markedly diminished. Studies of this patient's family show that this seems to be a genetically transmitted autosomal dominant trait. Unfortunately, one cannot arrive at simple answers from this observation because there is not a one-to-one concordance between the trait and the manifestation of clinical manic-depressive illness: the patient's father had an identical defect but no recorded affective disorder, although he appears not quite psychologically normal. The Chicago group also finds some but not all manic-depres-

sive patients with a similar defect, suggesting a subgroup. This defect is not fo
in schizophrenic or in unipolar depressed patients.

The Pennsylvania group reports their continuing work, which is both basic
clinical. They agree with the Chicago group about the mechanisms involve
influx of Li^+ into cells and the method of efflux. They feel that the great ir
subject variance is related to variance in the efflux system. They continue to
the Li^+ ratio to be a predictor of beneficial effects of lithium for treatmen
prophylaxis, but their attempts to differentially diagnose unipolar from bi
patients by the ratio fail to reach statistical significance. They have develope
in vitro system in which the distribution of Li^+ between cells and the mediu
a .90 correlation with that found in vivo.

The Columbia group also agrees that the level of Li^+ in a cell is determ
primarily by its efflux rate and has also developed an in vitro system in v
RBCs are preloaded with Li^+ and the rate of efflux into an artificial mediu
directly measured. With this system they found no differences between pa
with affective disorders who were not on lithium and controls. However, the
find that chronic lithium administration lowers the efflux rate to a stable
significantly below the pretreatment state. Patients with lithium toxicity had l
even markedly lower.

These three papers are similar conceptually and methodologically to
found in the clinical pharmacology of internal medicine. They are sophistic
and difficult to read, but they show maturation in the research needed fo
understanding of the mode of action and optimum use of a very effective ps
tropic drug. Like all good research they raise many questions but offer me
for answering them, and they contribute simultaneously to basic physiology
cal pathogenesis, and therapeutics. It can safely be predicted that studies s
to these will continue with lithium and that the same principles of investig
will soon be applied to other psychotropic drugs and other illnesses.

TOPICAL PAPERS: Lithium Transport—New Research Findings

Clinical Correlates of the Lithium Pump

BY DAVID L. DUNNER, M.D., HERBERT L. MELTZER, PH.D., AND RONALD R. FIEVE, M.D.

The active efflux of lithium from erythrocytes, expressed as the rate constant k_o, was studied in patients with primary affective disorder and in controls. The authors' data suggest that k_o is stable within individuals over time, is inhibited during treatment with lithium carbonate, and may be a good index of lithium toxicity. k_o correlates significantly with the lithium erythrocyte/plasma ratio but is seemingly not related to age, sex, or affective disease subtype. Preliminary data suggest that k_o may be determined, at least in part, by a genetic factor.

RECENT STUDIES from our and other laboratories suggest that lithium movement across cell membranes is governed by active transport processes—the lithium pump. It can be shown that lithium is actively transported out of human erythrocytes (1, 2). The influx and efflux rates of transport across erythrocyte membranes can be expressed as rate constants (k_i and k_o, respectively), which define the fraction transported per hour. These rate constants can be assessed in subjects who are taking lithium carbonate and in drug-free individuals. The k_i/k_o ratio is fractional, i.e., the active transport process for lithium efflux from erythrocytes is greater than that for influx.

In this paper our purpose is to discuss some of the clinical correlates of the lithium pump. We will focus on the relationship of pump activity to the lithium erythrocyte/plasma ratio (Li^+ ratio), the effect of lithium administration on lithium pump activity, and a possible role of the lithium pump in lithium toxicity and present some preliminary data on lithium pump activity in genetically related individuals.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Dunner is Psychiatrist, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Meltzer is Research Scientist V (Neurochemistry) and Dr. Fieve is Chief of Research, Lithium Clinic and Metabolic Unit. The authors are also with Columbia University, where Dr. Dunner is Associate Professor of Clinical Psychiatry, Dr. Meltzer is Assistant Professor of Biochemistry, and Dr. Fieve is Professor of Clinical Psychiatry.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-21586 from the National Institute of Mental Health and by the Foundation for Depression and Manic Depression.

METHOD

Subjects in this study were outpatients of the New York State Psychiatric Institute Lithium Clinic or inpatients on the Metabolic Clinical Research Unit of the institute. All patients met the diagnostic criteria of Feighner and associates (3) for primary affective disorder and were further classified into bipolar and unipolar subgroups based on the criteria described by Fieve and Dunner (4). The relatives and spouses of patients were also studied, and psychiatric diagnoses for all individuals were established through a structured interview (5). All subjects gave informed consent to participate in these studies.

Heparanized blood for the study of lithium pump activity was obtained at various times and from patients in varying clinical states. For outpatients, most of whom were euthymic and were being maintained on lithium carbonate therapy, blood was obtained between 12 noon and 1 p.m., which was in most cases approximately 14 hours after the last dose of lithium carbonate. Mood state and other medications were

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

noted for outpatients (6). Blood from relatives of patients was obtained in the early afternoon, and blood from inpatients was obtained in the morning before breakfast (9–24 hours after the last lithium dose). Some inpatients were studied at weekly intervals.

Laboratory procedures for the study of the lithium pump are described in detail elsewhere (1). Briefly, the kinetics of lithium efflux were measured after suspension of erythrocytes in a modified Ringer's solution and incubation at 37° C. The efflux rate constants were obtained from the increase in lithium concentration in the Ringer's solution over a 2-hour period. Erythrocytes from subjects who had not been taking lithium carbonate were preincubated with a Ringer's solution containing 15–20 mEq/liter of lithium in order to preload the erythrocytes. This preloading was also performed in cells of patients who had been treated with lithium. Data for lithium pump activity are expressed as rate constants: k_o refers to the activity of the process that transports lithium out of erythrocytes, and k_i to lithium influx into erythrocytes. In our laboratory, measurements of k_o are considered more reliable than measurements of k_i because of certain technical problems in the assay for k_i. Units for these rate constants are per hour. For purposes of this report, the k_i/k_o ratio was calculated using uncorrected data for k_i (i.e., no correction for the effect of k_o on lithium accumulation in erythrocytes). In other reports we have applied such a correction factor, which entails multiplying the k_i/k_o ratio by approximately 1.2.

RESULTS

Lithium pump activity was assessed in 49 subjects who were not being treated with lithium carbonate (see table 1). The mean k_o (±SD) in these individuals was .258±.070. There was no significant correlation between k_o and age of subjects (r=.07), and there were no significant differences between mean k_o for men and women controls (t=.61). Similarly, there were no significant differences in mean k_o between groups of patients. The mean k_i/k_o ratio for all subjects was .17±.05.

The mean k_o in 81 subjects who were being treated with lithium (see table 1) was significantly different from that for subjects who were not being treated with lithium (t=7.51, p<.01). The mean k_o in the lithium group was significantly different from that in the non-lithium group (t=6.55, p<.01). There were no significant differences in mean k_o among the groups of lithium-treated patients.

The effect of lithium on k_o is further illustrated in table 2, which presents data from 6 patients who were studied before and during lithium treatment. All 6 showed a reduction in k_o with lithium treatment (paired t=5.32, p<.01), and 5 of the patients showed an increase in k_i/k_o (paired t=3.45, p<.02).

The stability of k_o over time in 25 lithium patients (and 1 non-lithium-treated control) is illustrated by considering data from patients who were treated with lithium for longer than 2 weeks. Preliminary data suggest that k_o will decrease with time. The mean k_o during early stages of treatment was almost identical with the mean 2 weeks later (means=.190±.073 and .189±.071, respectively, range of repeated determinations 2 weeks). The correlation coefficient between initial and later measurements was high (r=.96, p<.01).

The relationship of lithium pump activity to the Li^+/Na^+ ratio could be assessed in 53 subjects. In these subjects, the pump activity and the Li^+/Na^+ ratio were determined from blood samples taken during the same clinic visit. The Pearson's correlation coefficient for the relationship between the k_i/k_o ratio and the Li^+/Na^+ ratio was r=.49 (p<.01). The correlation for the relationship between k_o to the Li^+ ratio was r=−.47 (p<.01). The relationship between k_i and the Li^+ ratio was not significant.

Several relatives of patients volunteered for the research study. To analyze these data, we examined the k_o correlation in 15 pairs of first-degree relatives.

*Statistically higher than during lithium, paired $t=5.32$, $p<.01$.
**Statistically lower than during lithium, paired $t=3.45$, $p<.02$.

including probands and first-degree relatives if the proband was not treated with lithium. We also computed the correlation for 4 pairs of subjects who were not genetically related but who were living in the same household—these subjects were parents of probands. A high correlation was found between first-degree relatives ($r=.65$, $p<.01$), but the correlation between nongenetically related subjects was lower ($r=.38$). Furthermore, the correlation for 23 pairs of "random" non-lithium subjects who were not genetically related was $r=.12$ (n.s.).

We were able to study k_o in 2 patients who were admitted during states of lithium toxicity. Both patients showed reduction in k_o during lithium toxicity (values of .088 and .148) compared with later analysis in the Lithium Clinic (values of .176 and .178).

DISCUSSION

Activity of the lithium pump can be determined in individuals regardless of whether they are being treated with lithium carbonate. For this paper, we analyzed data on the lithium pump up to March 1, 1977. It should be noted that our studies of the lithium pump are continuing, and we plan to augment the data presented here with data on more subjects.

The data we have obtained thus far reveal several facts about the lithium pump. In subjects who are not being treated with lithium carbonate, k_o does not seem to be related to age, sex, or diagnosis. k_o appears to be stable over time and may be determined, at least in part, by a genetic factor. During lithium treatment k_o is considerably reduced, and there may be even further inhibition of k_o during lithium toxicity. A significant correlation can be demonstrated between the activity of the lithium pump and the Li^+ ratio.

Many questions regarding the lithium pump remain for further study. Preliminary data suggest that the activity of the lithium pump may correlate with the outcome of lithium prophylaxis (7). Also, there appears to be a critical dose of lithium that will cause inhibition of the lithium pump, and the relationship of this dose to therapeutic plasma lithium concentration requires further study (7). Other issues, such as the relationship of the efflux pump to lithium plasma concentrations, the mechanism of inhibition of the pump by the lithium ion, and the relationship of the lithium pump to other ions (e.g., calcium and magnesium) and to other cation transport mechanisms, await further study.

Our data suggest a possible role of the efflux pump in lithium toxicity. In this speculative model, lithium toxicity could be defined as occurring when the lithium efflux pump is inhibited beyond the usual inhibition that occurs with lithium treatment. Inhibition of the efflux pump would lead to higher intracellular lithium ion concentrations (and abnormally elevated Li^+ ratios). Treatment of lithium toxicity would entail treating the inhibition of the lithium pump. According to this model, changes in the lithium efflux pump activity and/or the lithium erythrocyte/plasma ratio would reflect and parallel clinical changes during lithium toxicity as the high intracellular lithium load is transported to the extracellular fluid compartments.

Erythrocyte Concentrations of the Lithium Ion: Clinical Correlates and Mechanisms of Action

BY ALAN FRAZER, PH.D., JOE MENDELS, M.D., DAVID BRUNSWICK, PH.D., JACK LONDON, PH.D., MARTIN PRING, PH.D., T. ALAN RAMSEY, M.D., AND JANUSZ RYBAKOWSKI, M.D.

When lithium carbonate is administered to individuals, there is considerable intersubject variation in the extent of accumulation of Li^+ by erythrocytes. The primary reason for this is differences in the activity of a Li^+-Na^+ counterflow system, which, under clinical conditions, removes Li^+ from the cell. It appears that some bipolar patients accumulate more Li^+ in their red cells than either unipolar depressives or normal controls. The precise clinical characteristics of the bipolar patients who accumulate relatively large amounts of erythrocyte Li^+ need to be clarified in future research. Finally, the measurement of red cell concentrations of Li^+, in addition to the usual plasma measurement, can be used as an indicator of patient compliance.

EXTENSIVE RESEARCH has been stimulated by our observations (1–4) suggesting that study of the relative accumulation of the lithium ion (Li^+) by erythrocytes (RBCs), expressed as the ratio of lithium in the erythrocyte to its concentration in plasma (Li^+ ratio), might help identify a distinct subgroup of depressed patients and perhaps even a biological abnormality in these patients. This work has included examination of a variety of clinical phenomena that might be associated with variations in the distribution of Li^+ across the erythrocyte membrane, as well as the physiological mechanisms involved in transfer of Li^+ across this membrane. In this paper, we will review the current status of this continuing research.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Frazer, Brunswick, Ramsey, and Rybakowski are associated. Dr. Frazer is also Associate Professor of Pharmacology in Psychiatry, Department of Psychiatry, University of Pennsylvania School of Medicine, where Dr. Mendels is Professor of Psychiatry, Dr. Ramsey is Assistant Clinical Professor of Psychiatry, and Dr. Rybakowski is Research Fellow; Dr. London is Chief, Computer Section, Department of Medicine, and Dr. Pring is Associate Professor of Physiology. Dr. Rybakowski is also a Fogarty International Research Fellow.

This work was supported by research funds from the Veterans Administration and by Alcohol, Drug Abuse, and Mental Health grant MH-25433 from the National Institute of Mental Health.

Our initial study (1) involved 13 depres[sed] pitalized on a research ward. Several [ob]servations were made when erythrocyte [con]trations were measured simultaneously [with] levels of the cation. Although there was [some] intersubject variation (about twofold) [in] of the Li^+ ratio (a similar variability ha[d] earlier by Maggs [5] in a small group of st[ud]. was good intrasubject stability in the [same] time. All of the subjects had less lithi[um] cytes than in plasma, implying that unde[r] conditions Li^+ is not being distributed [in] with Gibbs-Donnan equilibrium. Two q[ues]from these observations: 1) What is the [basis] intersubject variability? 2) What facto[rs] transfer of Li^+ across the red cell mem[brane]?

Our initial study noted that the depr[essed] who improved with lithium carbonate de[fined] er Li^+ ratios than the nonresponders ([.]39±.02, $p<.005$, Mann-Whitney U te[st]. we were not able to replicate this find[ing] (as yet unpublished) study (see table 1) [of] the initial study, the second study inclu[ded] of outpatients and women. We reviewed [in] the original study to determine whether [any] factor might account for the difference [in] between the two studies. Variables such [as] illness, dosage of lithium carbonate, an[d] centration of Li^+ do not seem to acco[unt] parity in the results.

One factor that might provide an e[xplan]these apparently discrepant results is [the] between unipolar and bipolar affective [ill]the 9 lithium responders in the first stu[dy] affective illness, whereas 50% of the [non]were diagnosed as unipolar depressives [(]tion between a positive antidepressant [re]lithium carbonate and the diagnosis of [bi]has been noted before (see reference (6[)]). study, the 3 bipolar patients who did [not] treatment with lithium carbonate had [low] Li^+ ratios. In the second study, although [the] tion between bipolar illness and a posit[ive] sant response to lithium carbonate pers[ists] the 4 bipolar patients who did not respo[nd] high mean Li^+ ratio (.61±.06). Thus, w[hile] not be an association between the anti[de]fectiveness of lithium and the Li^+ rat[io].

Unipolar responders	4	.36	.04	.84	.03
Unipolar nonresponders	8	.44	.07	.88	.05

difference in the Li^+ ratio between unipolar and bipolar diagnostic subgroups. It may have been this association between the Li^+ ratio and diagnosis that we misinterpreted as an association with the antidepressant response in our initial report.

We have examined this question in a large sample of patients and have noted a significant difference ($p<.03$) between the Li^+ ratio in 23 unipolar patients (mean=.41, SEM=.03) and 29 bipolar patients (mean=.52, SEM=.02), with the difference being most pronounced for men. In the bipolar group, the clinical state, i.e., depressed, hypomanic, or manic, had no apparent effect on the Li^+ ratio. This suggests that the ratio may be a trait rather than a state variable.

While other investigators have also reported differences in the Li^+ ratio between unipolar and bipolar patients (9, 10), this has not been a consistent observation (11–14). Factors that might contribute to this inconsistency will be discussed later in this paper.

It must be emphasized that the Li^+ ratio cannot be used to make the diagnosis of unipolar or bipolar illness, even in men, because there is clearly substantial overlap between the groups. However, part of the variance in the Li^+ ratio between the subjects we have studied can be accounted for by the unipolar-bipolar distinction.

Comparisons of lithium erythrocyte/plasma ratios for patients and normal volunteers indicate that the ratio tends to be higher in the bipolar patients. Data on normal volunteers are still very limited (2, 8, 15), and many of these subjects have taken lithium for a short time and have relatively low plasma lithium concentrations. We have recently given 21 normal subjects daily doses of lithium carbonate for 21 days. In these subjects, the mean plasma concentration of Li^+, measured between days 7 and 21 of lithium administration, was .76±.02 mEq/liter and the Li^+ ratio was .46±.02. The difference in the mean ratios between this group of normal subjects and the bipolar patients studied earlier just fails to reach statistical significance ($.05<p<.10$). Recently, using an in vitro test to predict the Li^+ ratio (16), we have noted a significant difference in the mean ratios in 79 bipolar patients and in 49 non-psychiatrically-ill control subjects (17).

It thus appears that bipolar patients are more likely to develop high Li^+ ratios than are unipolar or control subjects. It remains unknown whether this is a characteristic of some bipolar patients (it has been suggested that bipolar illness may include at least two genetic subtypes [18]) or an as yet undefined subgroup of depressed patients that overlaps with (or is independent of) the bipolar-unipolar dichotomy.

Because of the importance of long-term maintenance treatment with lithium carbonate in selected patients, we have also examined the relationship between a beneficial "prophylactic" effect from lithium and the Li^+ ratio. A preliminary retrospective study involving 31 patients with recurrent affective disorders was conducted in association with Dr. A. Kukopulos and associates in Rome, Italy (see reference 4). The patients who benefited from lithium prophylaxis had a significantly higher mean Li^+ ratio than the nonresponders (.66±.03 versus .44±.03, $p<.001$, Mann-Whitney U test).

This observation remains controversial. Several investigators (19, 20) have reported that patients who have responded well to lithium treatment for periods ranging from 6 months to 4 years had significantly higher ratios than patients who relapsed. However, others (10, 21) have been unable to replicate these results. Clearly, what is needed is a properly controlled prospective study of the effectiveness of long-term maintenance treatment with the lithium ion as it relates to the Li^+ ratio.

METHODOLOGIC ISSUES IN LI^+ RATIO RESEARCH

There is substantial disagreement among investigators as to the clinical significance of the Li^+ ratio. Although the "positive" claims may be in error because of such factors as small, biased patient samples, it is also possible that important methodologic differences between studies may be responsible for the lack of agreement. It is important to consider what these methodologic factors might be and to control for them in future studies. Similar controversy and inconsistency surrounds almost all biological measures in psychiatry, including reports of biogenic amine and psychoendocrine abnormalities (see reference 22).

Of initial importance are the clinical criteria for treatment response and for diagnosis. These problems have been extensively discussed elsewhere (23–25) and need not be detailed here. However, it is clear that differences in these criteria could be a major source of inconsistencies. The use of standardized diagnostic criteria, e.g., those of Feighner and associates (26) or the modifications embodied in the *Research Diagnostic Criteria* (27), would obviously be of help in reducing this problem.

There are also several important technical problems that have not been approached in a consistent fashion by all investigators; these will be discussed below.

Direct Versus Indirect Measurement of Erythrocyte Lithium Concentration

Several groups of investigators (7, 8, 10) have used an "indirect" method (i.e., assessing the difference between whole blood lithium concentration and plasma lithium concentration) to measure erythrocyte Li^+ concentration. We have recently shown (28) that this indirect method gives much more variable, and presumably less accurate, results than values obtained by measuring the concentration of the cation in a hemolyzate made directly from packed erythrocytes. It appears to be relatively unreliable to calculate a mean value for an individual subject when using the indirect method unless there are a number of separate values for each subject.

Compliance with Lithium Medication Regimens

Medication compliance is a major problem for all studies that include outpatients. Our initial observations in hospitalized patients indicated that the intraindividual Li^+ ratio was relatively stable over time (1), but we have seen considerably more intraindividual variation over time in outpatients. The possible contribution of poor medication compliance to the variability in the Li^+ ratio has been demonstrated as follows: Venous blood was drawn from 6 patients receiving lithium carbonate—first in the morning after no lithium had been ingested for 12–14 hours (as is standard practice) and then 2 hours after a morning dose of 300 mg. As shown in table 2, the mean Li^+ ratio on the second occasion was significantly lower than that on the first occasion (29).

Thus, outpatients who accidentally or deliberately take a morning dose of lithium before having blood drawn may have spuriously low Li^+ ratios. This effect would be exaggerated if doses larger than 300 mg of lithium carbonate were taken before blood was drawn. These data suggest that the Li^+ ratio might be used as an indicator of patient compliance. Measurement of the plasma concentration of the cation alone may be misleading, since apparently therapeutic levels of plasma Li^+ can be achieved even if the patient has missed many doses over the preceding few days. However, significant swings in the Li^+ ratio over repeated visits probably indicate that an individual has not been taking the drug according to the schedule prescribed. Compliance problems may also be partly responsible for the alleged effect of plasma Li^+ on the magnitude of the Li^+ ratio (30).

TABLE 2
Effect of a 300-mg Morning Dose of Lithium Carbonate on Li Ratio

TRANSFER OF LI^+ ACROSS THE ERYTHROCYTE MEMBRANE

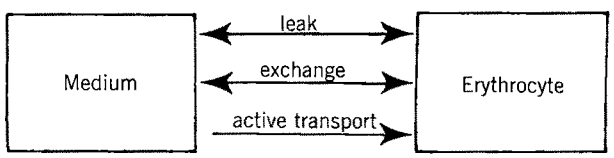
Despite the continued uncertainty about the clinical significance of differences in the Li^+ ratio, considerable attention has been directed to the examination of factors that determine the distribution of Li^+ across the erythrocyte membrane, in an effort to understand the considerable intersubject variation obs investigators. This body of work indicates ium ion can move into the red cell by th mechanisms: 1) diffusion down a concen ent, a "leak" process that appears to be the presence of bicarbonate ion in the me transport of the K^+ site of the Na, K-activ sine triphosphatase (ATPase) (31, 32); an into the cell in exchange for an internal (Na^+), a Li^+-Na^+ counterflow system or e fusion system (33–35).

Only two processes appear to be involv flux of Li^+ from the cell because under cl vant conditions there is no active transpo of the cell on the Na^+ site of the Na, K ATPase (32, 36). These processes are diffu concentration gradient or transfer out by counterflow or exchange system.

Under clinical conditions, the concent in the cell appears to be determined prima ance between its entry by diffusion down tion gradient (higher concentration in pl the cell) and its removal by the Li^+-Na system. The other mechanisms listed abov relatively less important.

We have recently used computer sim nonlinear regression techniques to inves of these factors is responsible primarily subject variation in the magnitude of the an initial study (37), it was shown that interindividual variation is related pri ferent rates of efflux of Li^+ from the cel

Based on the factors cited above, we oped a more sophisticated model of the t esses (see figure 1), which takes into acco tant physiological factor: the effect of se Li^+ transfer. This model generates th equation shown at the bottom of figure 1 calculated the three unknown constants tion, k_{leak}, $k_{exchange}$ and $flux_{active}$, by mea take by red cells in vitro and using the gression techniques mentioned above.



The results obtained for 7 subjects st

*$Flux_{active}$=0 in the presence of ouabain.

are shown in table 3. Inspection of the data reveals that the values for k_{leak} vary only about twofold between subjects; furthermore, it is obvious that there is no correlation between the magnitude of the rate constant for the leak process and that of the Li^+ ratio actually measured. It may be concluded, therefore, that passive diffusion of Li^+ in vitro shows little variation among individuals and cannot explain interindividual differences in the magnitude of the Li^+ ratio.

Similarly, there is no obvious relationship between the rate constant for Li^+ movement on the K^+ site of the Na, K-activated ATPase (i.e., $flux_{active}$) and the magnitude of the experimentally determined Li^+ ratio. In contrast, values for $k_{exchange}$ are related inversely to the Li^+ ratio, and also vary by a factor of approximately sevenfold among subjects. Therefore, intersubject variability in the magnitude of the Li^+ ratio probably results primarily from differences in the rate of the Li^+-Na^+ counterflow or exchange diffusion process, a system that drives Li^+ out of the cell. Low values of $k_{exchange}$ for an individual may result from either a lesser number of carrier sites or turnover of the sites (i.e., a lower V_{max}), a lesser affinity of the substrate for the sites (K_m), or both. A kinetic analysis by Duhm and Becker (38), using data from 4 control subjects, indicates that it is the number of carrier sites (V_{max}), rather than the affinity constants that varies among individuals.

These results indicated that it was reasonable to assume that if an in vitro system were developed by which Li^+ movement between cells and medium occurred primarily by the activity of the Li^+-Na^+ counterflow system, then the distribution of Li^+ between cells and medium measured in such a system would correlate highly with the distribution observed clinically. We have developed such a system (16) and have noted a very high correlation ($r>.90$) between the Li^+ ratio measured clinically and that measured in RBCs after a 24-hour incubation in an artificial plasma-like medium. Systems similar to ours have also been developed by Greil and associates (39) and by Pandey and associates (40) and have yielded correlations with the in vivo Li^+ ratio very similar to those we have found. Such systems should prove useful for further investigations into the relevance of the erythrocyte accumulation of Li^+ to the pathogenesis and treatment of affective disorders.

CONCLUSIONS

The uncertainties and problems surrounding our understanding of the clinical significance of the variations in the rate of Li^+ accumulation in erythrocytes are not dissimilar to the problems associated with other "systems" in biological psychiatry. Initially intriguing findings, partial replications, numerous methodologic problems, and small sample sizes for most studies seem to be a repetitive pattern. There is an urgent need for more carefully designed studies, adequate numbers of appropriately defined patients, and control data. Some of the issues are now more adequately defined insofar as this system is concerned, and, in particular, the development of a reliable in vitro procedure allows us to study large numbers of control subjects. These data should be crucial in clarifying the clinical significance of this system. In the meantime, we have gained important physiological information about the passage of the lithium ion across cell membranes that has served to focus our attention on the broader issue of possible abnormalities in transport systems and affective illness.

A Heritable Disorder of Lithium Transport in Erythrocytes of a Subpopulation of Manic-Depressive Patients

BY DAVID G. OSTROW, M.D., PH.D., GYANSHYAM N. PANDEY, PH.D., JOHN M. DAVIS, M.D., STEPHEN W. HURT, M.A., AND DANIEL C. TOSTESON, M.D.

The in vivo RBC/plasma Li^+ ratio is determined by the equilibrium between Li^+ influx (ouabain-sensitive Na^+-K^+ pump and ouabain-insensitive leakage pathways) and Li^+ efflux (phloretin-sensitive Li^+-Na^+ counterflow). A study of RBC Li^+ transport via these pathways showed that a deficiency of Li^+-Na^+ counterflow was responsible for the high in vivo ratio (1:1) observed in a manic patient. This defect was related to an alteration in the membrane Na^+ exchange system and was under genetic control. The level of counterflow before lithium therapy was an excellent predictor ($r=.88$) of the in vivo Li^+ ratio and was deficient in approximately one-fourth of manic-depressive patients but not in controls, schizophrenics, or unipolar depressed patients.

LITHIUM IS EFFECTIVE in the treatment of manic-depressive (bipolar affective) illness (1, 2). The red blood cell/plasma lithium concentration ratio (Li^+ ratio) is relatively constant for each individual (3), a fact that has led to considerable interest in whether or not the in vivo Li^+ ratio in bipolar patients differs from that in normal individuals (4) and/or is related to response to lithium therapy (3, 5, 6). Recent in vivo and in vitro studies in normal subjects have demonstrated that genetic factors contribute to interindividual differences in the ratio (7, 8), and family studies have shown a genetic predisposition to bipolar affective illness (9). The above lines of investigation have led to explorations of the biochemical mechanisms underlying the maintenance of the Li^+ ratio in human RBCs (10–13). It is of interest to examine the question of whether any of those factors that control the Li^+ ratio themselves may be under genetic control.

Although alkali cation transport processes are complex, they can be schematically divided into three major mechanisms. Under normal physiological conditions, the ouabain-sensitive Na^+-K^+ pump actively transports these ions uphill, potassium into the cell and sodium from the cell to the extracellular medium (14). Another mechanism of sodium transport by cell membranes is the sodium-sodium exchange pathway, which allows for the stoichiometric exchange of intracellular for extracellular sodium ions and therefore cannot be responsible for net uphill transport of sodium but rather functions as a facilitated exchange diffusion pathway (15, 16). Finally, there is the downhill leakage of cations along their concentration gradient. We have characterized three distinct pathways of lithium transport, which resemble the three pathways described for sodium-potassium transport (see figure 1) (10–13). These three pathways are operationally distinguishable by virtue of their differential sensitivities to ouabain and phloretin. In the first pathway, lithium is transported by the inward loop of the ouabain-sensitive Na^+-K^+ pump, the loop normally used by K^+ (11). Lithium can also be transported by a Li^+-Na^+ counterflow system, which results in the transport of lithium in the direction opposite to that of the sodium gradient and is inhibited by phloretin (11, 12). Finally, lithium can diffuse through inhibitor insensitive pathway(s) down its chemical concentration gradient. Under normal physiological conditions, namely $[Na]_{rbc}=5$–10 mEq/liter and $[Na]_{plasma}=140$ mEq/liter, the phloretin-sensitive Li^+-Na^+ counterflow system operates to extrude Li^+, and the concentration of Li^+ is maintained at a level 2–3 times higher in the plasma than in the RBC. Thus, the steady-state distribution of lithium between the red cell and plasma in vivo depends primarily on the balance between influx via the insensitive leakage pathway(s) and efflux via the phloretin-sensitive Li^+-Na^+ counterflow system. This picture of lith-

FIGURE 1
Transport Determinants of the In Vivo Li^+ Ratio

ium transport has been confirmed by several independent groups of investigators (13, 17, 18).

As shown in figure 1, alterations in the balance between these various pathways can result in large changes in the intracellular/extracellular lithium ratio. For example, if the insensitive leakage pathways were negligible and only the Li^+-Na^+ counterflow system were operating, the distribution of Li^+ between the inside and outside of the cell would be identical to the distribution of Na^+, giving a ratio of approximately 0.06 (see figure 1, lower right). In contrast, if the influx pathways were operative and the Li^+-Na^+ counterflow system negligible in RBCs (see figure 1, lower left), the distribution of Li^+ in the steady state would be determined predominantly by the electrochemical potential of the cell, and the ratio would be approximately 0.8–1.0 (15). We already know that most individuals on lithium have a ratio in the range of 0.3–0.5, indicating a dynamic balance between influx of Li^+ via the leakage and ouabain-sensitive pathways and efflux via the Li^+-Na^+ counterflow system.

In the course of our study of Li^+ transport in both normal individuals and patients with affective disorders, we observed a patient with a Li^+ ratio of 1.0. We found that this increased ratio is the result of a deficiency or defect in this individual's RBC phloretin-sensitive Li^+-Na^+ counterflow pathway, which is related to the Na^+ exchange diffusion system of the membrane, and that this defect is genetically transmitted. In addition, we have demonstrated that this decrease in phloretin-sensitive Li^+ transport is found in the RBCs of a subgroup of manic-depressive individuals. Some of these findings have been presented in preliminary reports (19, 20).

METHOD

Subjects

Control subjects were employees of either the Department of Research at Illinois State Psychiatric Institute (ISPI, a state hospital) or the Depart... chiatry, Michael Reese Hospital and Med... (MRH-MC, a private psychiatric hospital) ... subjects were screened for medical or psy... orders and were without history of affecti... first-degree relatives.

Psychiatric patients were either hospit... research wards at ISPI (including the 21-... described below) or were manic-depressiv... or outpatients at MRH-MC. All psychiat... were diagnosed by both *DSM-II* (21) and ... teria and gave written informed consent be... pating in the study. Inpatients were all ... cept for the manic-depressive patients o... the time of transport measurement, the ... patients for a minimum of 2–3 weeks an... MC patients for varying lengths of time. †Data from Lyttkens and associates' study of normal women (4); other control data are from our sample of normal men.

hour in a medium containing 40 mM lithium chloride in a sodium chloride medium. Following this, the cells were washed and then suspended in a medium containing 1.5 mEq/liter of lithium in 135 mM sodium chloride, and the change in internal lithium in the presence and absence of 10^{-4} M phloretin was determined (20).

Those patients diagnosed as having bipolar affective illness were placed on lithium therapy according to a standard research protocol that is used on our units. Following attainment of a steady-state lithium dosage, blood was drawn from these individuals on several occasions for determination of the in vivo lithium ratio (5). In addition, a sample of blood was obtained from patients on a steady-state lithium dosage for redetermination of lithium influx rates and phloretin-sensitive Li^+-Na^+ counterflow.

In vivo and in vitro Li^+ ratio values are expressed as (milliequivalents of lithium per liter of RBCs)/(milliequivalents of lithium per liter of plasma or media).

Analytical Procedures and Reagents

Cells and medium were analyzed for K^+, Na^+, and Li^+ by atomic absorption spectrophotometry, for hemoglobin by spectrophotometry, and for water content by weighing before and after drying at 110° C for 14 hours. ^{22}Na was measured in the medium and cells by counting the gamma radiation in a crystal scintillation spectrometer.

Statistical Methods

Linear Li^+ influx rates were determined independently in each half of the patient's blood sample by regression analysis of the RBC Li^+ concentrations determined at 0, 1, and 2 hours of incubation. Values used in the analyses were averages of the values from each half of the sample. Assays that proved to be poorly estimated by a linear regression ($r^2<.85$) were discarded and redetermined. Significance of group differences was determined by two-tailed t tests using the 95% confidence level.

RESULTS

In the course of studying lithium transport parameters of normal control subjects and manic-depressive patients, we discovered a patient whose Li^+ ratio of 1.0 indicated a severe derangement of lithium transport. The characterization of the defect of lithium transport in this patient is followed by the overall results of our studies in normal and patient samples.

High Lithium Ratio in One Patient

Table 2 shows the in vitro and in vivo lithium ratio in a 21-year-old black man admitted after a week of overactivity, restlessness, insomnia, pressure of speech, tangential associations, euphoria, and grandiose ideas related to his forthcoming graduation. This was the patient's first psychiatric admission, and he fulfilled both the *RDC* and *DSM-II* criteria for manic illness.

During the first 2 weeks of lithium treatment his affect normalized, his thinking slowed and became more organized, and grandiose, delusional thinking abated.

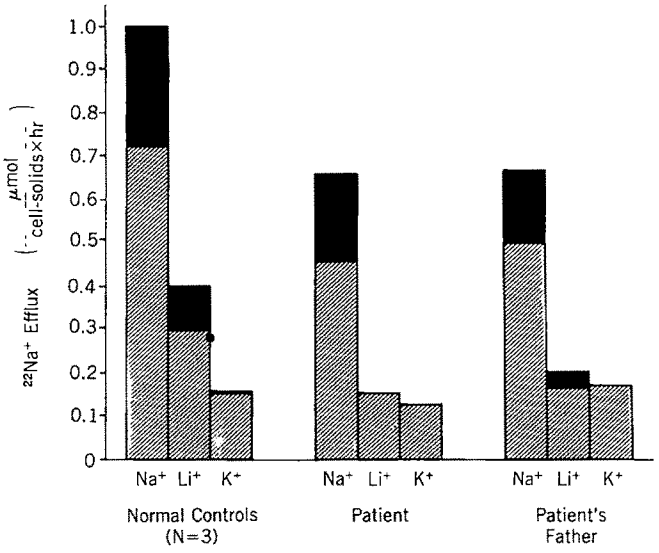
He was discharged after 6 weeks of hospitalization, during which his behavior returned to normal, and was maintained on 1800 mg/day of lithium carbonate for the next 5 months. Lithium was discontinued 1 year ago, and the patient has done well since then.

As can be seen in table 2, the Li^+ ratios for this patient both before and during lithium therapy were approximately 3 times higher than those seen in normal controls for the same periods. The patient's ratio during lithium treatment approaches the passive distribution of a monovalent cation across the RBC membrane (15), suggesting an absence of or defect(s) in the pathway(s) responsible for the maintenance of the normal lithium ratio. One such pathway, the phloretin-sensitive Li^+-Na^+ counterflow pathway, was significantly reduced in this patient before and after treatment in comparison with normal controls and was also reduced by lithium treatment (table 2). Other pathways were normal or slightly elevated in this patient (see table 3).

The close relationship between phloretin-sensitive Na^+-Na^+ exchange and phloretin-sensitive Li^+-Na^+ counterflow (23) suggested an investigation of this pathway using Na^+, Li^+, or K^+ as the external monovalent cation. Both the patient and the patient's father, who also showed a significantly decreased Li^+-Na^+ counterflow, demonstrated a near or total absence of phloretin-sensitive, Li^+-stimulated sodium exchange (figure 2).



To determine the locus of the defect, RBCs from the patient and a normal control were preloaded to a lithium content of 1.3 mEq/liter and suspended in plasma from both individuals. Plasma contained 1.5 mEq of lithium per liter. The patient's cells were unable to extrude lithium in his own or the control plasma, while control cells extruded similar amounts in both patient and control plasma (.50 and .46 mEq/lite... ly, in 4 hours). Moreover, the results of ... hematologic work-up found no cytoplasm... might account for the patient's defective ce...

Transport Parameters in Patient Groups

Figures 4–6 show the individual results and group means of the various lithium influx rates as measured in controls, manic-depressives, and schizophrenics. None of these patients was receiving any medication, including lithium, at the time of the study. We observed a decrease in phloretin-sensitive Li^+ influx measured in magnesium chloride medium in the manic-depressive group only (figure 4). Mean ouabain-sensitive Li^+ influx (figure 5) was significantly increased in both the manic-depressive ($p < .02$) and schizophrenic ($p < .03$) groups. We also observed a significant increase in inhibitor-insensitive Li^+ influx in the manic-depressive group, while this parameter, measured in a small group of schizophrenic patients, clustered at the low end of the normal range (figure 6). Unipolar depressives (10 patients) as a group showed no alteration in any lithium transport parameter, while RBCs from unipolar depressives with hypomania (bipolar II, N=7) had as a group increased phloretin-sensitive Li^+ influx ($p<.05$).

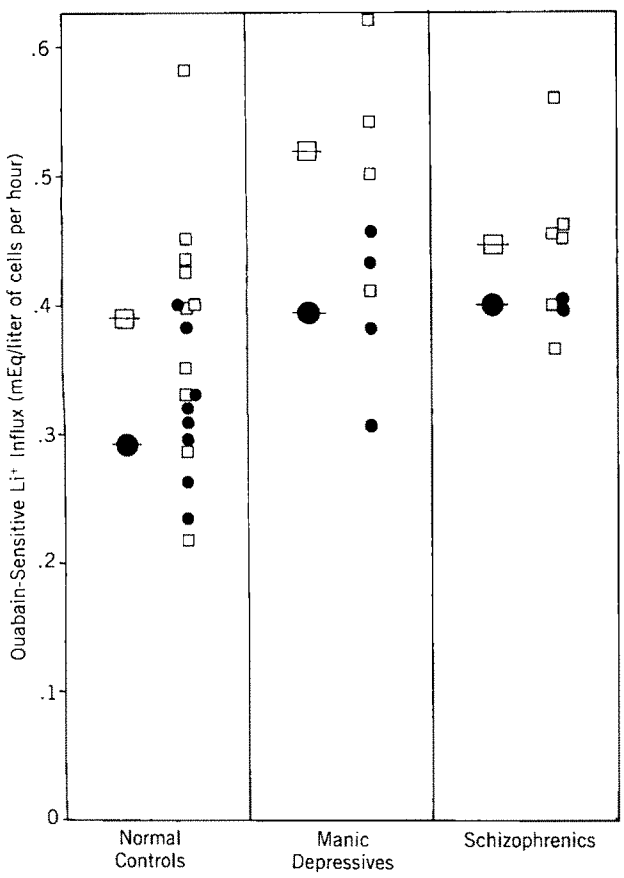

Table 4 gives direct measurements of phloretin-sensitive Li^+-Na^+ counterflow in normal subjects, schizophrenics, and manic-depressives either before or during lithium therapy. Again, manic-depressives, as a group, showed lower average Li^+-Na^+ counterflow than did normal subjects, due largely to the difference between manic-depressive subjects and male control subjects. Female manic-depressives had counterflow rates similar to female control subjects. However, the counterflow level in RBCs from female controls was significantly lower than that in male controls ($p<.005$). Note also that there was a decreased counterflow level in both male and female subjects on lithium at the time of assay. Although the overall group means do not show a statistically significant decrease due to lithium therapy, when the subset of 8 subjects whose counterflow levels were measured both before and during lithium therapy were examined individually, there was a uniform 35%–45% decrease in Li^+-Na^+ counterflow in response to the treatment.

Correlation Between In Vitro Li^+-Na^+ Counterflow and In Vivo Li^+ Ratio

Figure 7 shows the correlation (r=.88) between the in vitro measurement of RBC Li^+-Na^+ counterflow before lithium therapy and the actual in vivo Li^+ ratio observed during steady-state lithium therapy in our group of manic-depressive patients. Simi[illegible] tions were obtained using both net coun[illegible] phloretin-sensitive counterflow measure[illegible] indicates that although we observed a very [illegible] of values for both phloretin-sensitive Li^+ [illegible] in vivo Li^+ ratio in manic-depressive patie[illegible] predict the intracellular Li^+ level attained [illegible]

FIGURE 7
Correlation of In Vitro Li^+-Na^+ Counterflow Measurements with the In Vivo Li^+ Ratio*

*Phloretin-sensitive Li^+-Na^+ counterflow was measured in duplicate before lithium therapy; in vivo Li^+ ratio was measured 3–10 times during steady-state lithium therapy. Open symbols indicate ISPI patients and closed symbols indicate MRH-MC patients. Circles indicate females, squares males.

py quite accurately based on the in vitro measurement of Li^+ transport before the institution of lithium therapy. This high correlation between in vitro counterflow measurements and in vivo ratio was unique among the transport parameters studied (23), indicating the relative importance of phloretin-sensitive Li^+-Na^+ counterflow as a determinant of the steady-state intracellular Li^+ level at a given plasma Li^+ level. Figure 7 also redemonstrates the existence of a subgroup of manic-depressive patients whose red cells possess an abnormally low degree of Li^+-Na^+ counterflow and hence develop abnormally high lithium ratios on lithium therapy.

SUMMARY AND DISCUSSION

The major findings of this clinical study of lithium transport are as follows:

1. The in vivo Li^+ ratio is determined by the dynamic balance between the phloretin-sensitive Li^+-Na^+ counterflow and lithium leakage pathways.
2. Approximately one-fourth of the manic-depressive patients had a marked deficiency in phloretin-sensitive Li^+-Na^+ counterflow, resulting in markedly increased in vivo and in vitro Li^+ ratios.
3. This defect in phloretin-sensitive Li^+ transport cannot be ascribed to either a plasma inhibitor or cytoplasmic factor but rather is an intrinsic property of the RBC membrane.
4. In the case of the patient and his family we studied in detail, the defect in lithium transport is genetically transmitted in a pattern consistent with dominant inheritance under autosomal control.
5. The only significant sex-related difference in lithium transport was the finding that normal males have significantly higher Li^+-Na^+ counterflow than do normal females. None of the parameters studied showed significant variations according to age or race.

Several questions arise concerning the possibility of a relationship between a heritable defect of lithium transport and manic-depressive illness. Our data and those of Duhm and Becker (24) on normal individuals have demonstrated substantial interindividual differences in lithium transport, and evidence from the twin study method indicates that genetic factors contribute to the steady-state Li^+ ratio in normal individuals (7, 8). Therefore, it is reasonable to assume that there may be substantial genetically controlled variability in the various moieties of lithium transport that determine the Li^+ ratio. Clearly, there is not a one-to-one relationship between bipolar affective illness and a Li^+-Na^+ counterflow deficiency. Our preliminary data have suggested that such a reduction in phloretin-sensitive lithium transport is found in a subgroup of manic-depressive patients and is not characteristic of schizophrenics or unipolar depressed patients. However, we have studied bipolar patients with Li^+ ratios and transport values within normal limits who have had good responses to lithium. The father of the manic patient in this report is an example of an individual with a severe RBC Li^+-Na^+ counterflow deficiency and no previously diagnosed major affective illness. However, this man has periodically and regularly absented himself from his family for periods of 1 week or more over the last 20 years, and three of his five siblings have been hospitalized for episodes of mania or depression. In contrast, there is no evidence of affective illness in any of the mother's siblings or her parents. Of possible significance in this regard is the fact that a 20-year-old woman who is next in this sibship and whose red cells lacked phloretin-sensitive Li^+-Na^+ counterflow (sibling 2) has had a major depressive episode.

Additional work must be done to further define the

genetic mechanism involved in the inheritance of the lithium transport system(s). As a reduction in Li^+-Na^+ counterflow is apparently the mechanism that accounts for the elevated Li^+ ratio seen in some bipolar patients, direct measurements of transport moieties may help us to characterize possible subgroups of bipolar patients. In addition, longitudinal studies of apparently "normal" individuals with lithium transport abnormalities, such as sibling 7 in the family described here, may help us to unravel the relationship between such transport defects and susceptibility to and form of affective illness. The finding by Lyttkens and associates (4) that female patients on lithium have higher in vivo Li^+ ratios than do males can be explained by our finding that, on the average, women have a lower level of Li^+-Na^+ counterflow in their red cells than men do.

We hope that a clearer understanding of the biochemical determinants of the lithium ratio and the opportunity to measure these parameters in a large number of patients before the institution of lithium therapy will help clarify the conflicting data concerning the prediction of clinical response to lithium from the lithium ratio (3, 5, 6, 25–28). Methodologic problems in response studies such as small sample sizes and the lack of fixed-dose methodology render the results of such studies preliminary at best. Obviously only a large multicenter collaborative study of lithium transport parameters in a large number of normal subjects and patients with diverse psychiatric diagnoses can help to clarify these issues.

If there is a relationship between the mechanism and control of lithium transport and the pathophysiology of affective illness, what is the nature of that relationship? Our findings of a defect in lithium transport may indicate the presence of a defect in transport system(s) involved in the transport of physiologically significant ions. It is of considerable importance that the defect of lithium transport that we have described here is a deficiency of the Li^+-Na^+ counterflow system, which is mediated by lithium-sodium exchange. There has been considerable empirical evidence for a sodium transport abnormality in affective illness (29–31), and it has been suggested that a primary defect in affective illness may be an inherited defect resulting in a reduced capacity of the neuronal membrane to remove sodium from the cell (32). One can postulate that such an alteration of the cation-exchange system of the membrane might result in the decreased transport of compounds using pathways which require either the co-transport or countertransport of sodium ions. Catecholamine reuptake systems have an absolute requirement for sodium ions (33), and preliminary data from our laboratories indicate that phloretin is a very effective inhibitor of catecholamine reuptake systems (Javaid, Ostrow, Smith, and Davis, unpublished observations).

The finding of three distinct pathways of lithium transport and the demonstration of genetic transmission of a deficiency of lithium-sodium counterflow have implications for the clinical use of lithium. It has been suggested that the toxicity and efficacy of lithium are more closely related to red cell than to [illegible] ium levels (34). We have shown that subst[illegible] individual variability exists in the count[illegible] way of lithium transport, which may affec[illegible] central nervous system lithium concentra[illegible] even if the abnormality in lithium transpor[illegible] ally related to the pathogenesis of mani[illegible] illness, genetically controlled inte[illegible] ferences may be related to other parame[illegible] the time course of response to lithium the[illegible] tibility to lithium toxicity, and optimu[illegible] quirements for long-term lithium prophy[illegible]

BRIEF COMMUNICATIONS

Effect of Alcohol Consumption on State Anxiety Changes in and Female Nonalcoholics

BY PATRICK E. LOGUE, PH.D., W. DOYLE GENTRY, PH.D., MARKKU LINNOILA, M.D., AND C. WILLIAM ERWIN, M.D.

Ten male and 10 female nonalcoholic college students were given drinks having alcohol levels of 0, 0.5, 0.8, and 1.2 g/kg. They were then given four complex psychomotor tests, immediately before and after which they were given the Spielberger State Anxiety Inventory, and asked to rate their performance on a five-point scale. Mean anxiety change scores were −.90, .75, 4.75, and 5.55 for the four alcohol doses, respectively. There was no significant correlation between anxiety change and actual performance on the visual vigilance task, but for males there was a significant correlation between anxiety change and perceived level of impairment.

BOTH FOLKLORE and the bulk of the existing literature on alcoholism suggest that excessive alcohol consumption is a behavior pattern that is acquired and maintained because it reduces social anxiety and physiological tension. However, several recent studies (1–5) have indicated that alcohol may in fact lead to increased anxiety/tension rather than its reduction. Mendelson and associates (2) noted that alcoholic subjects experienced an increase in anxiety and depression during a 14-day period of experimental drinking and that the intensity of negative affect was related to the amount of alcohol consumed, i.e., the more the subjects drank the more anxious they became. McNamee and associates (3) also found a "paradoxical increase" in anxiety in 9 out of 12 (75%) chronic male alcoholics in an experimental drinking situation. Nathan and O'Brien (4) compared the drinking and affective behavior of 4 skid-row alcoholics and 4 matched nonalcoholics and reported that n... experienced reduced levels of anxiety w... On the contrary, the alcoholic subjects sho... ened levels of acute anxiety as soon as dri... whereas the nonalcoholic subjects showed ... no change in anxiety with alcohol.

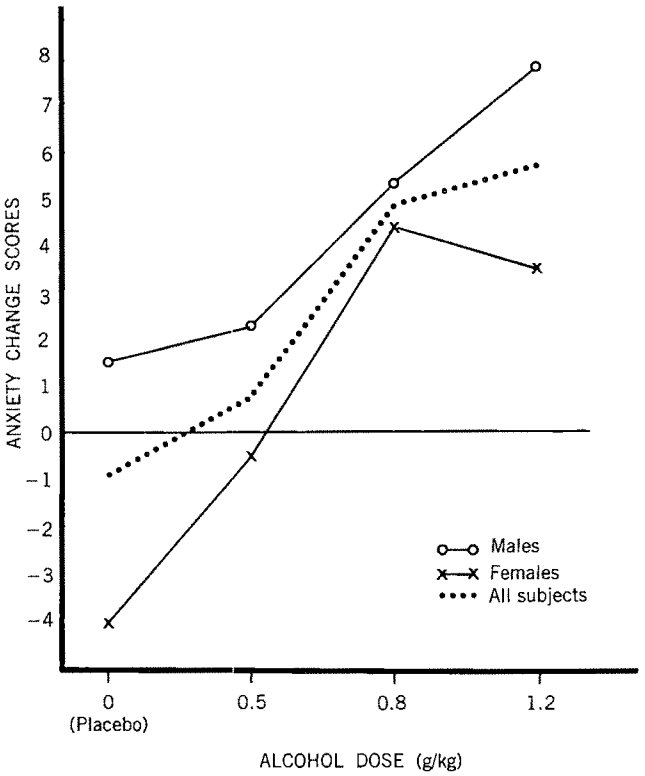
drinking was 30 minutes. To allow for even absorption of the alcohol, subjects were asked to fast for the 3 hours before each test session.

The subjects were trained to criterion on a battery of four complex psychomotor tests related to driving behavior: a measure of simple reaction time, a critical tracking task, a continuous performance task, and a visual vigilance task. They were then randomly assigned by means of a Latin square design to the various alcohol conditions. Drinks were administered in a double-blind fashion at the same time each day (3:00 p.m.), with the exception of a fifth experimental condition in which the medium 0.8 g/kg dose of alcohol was administered in the morning (9:00 a.m.) to assess circadian (rhythm) effects. Subjects were given the Spielberger State Anxiety Inventory (6), which takes about 5 minutes to complete, immediately before and after psychomotor test performance. This inventory is designed to measure "a transitory emotional state or condition of the human organism that is characterized by subjective, consciously perceived feelings of tension and apprehension, and heightened autonomic nervous system activity." The inventory requires the subject to respond in terms of how he or she feels at that moment to 20 items such as, "I am jittery," "I feel nervous," and "I feel self-confident." Subjects were also asked to rate their level of performance on the psychomotor test battery on a five-point scale ranging from "very good" (one) to "very impaired" (five) after each testing session.



Subjects were tested in the various alcohol conditions at weekly intervals, and all testing took place in a soundproof, air-conditioned room. Subjects were monitored by a TV camera and if necessary were contacted during the experiment by intercom, which presented recorded task instructions.

RESULTS

Anxiety change scores were computed by subtracting the score obtained after performance on the psychomotor tests from the score obtained before testing in each alcohol condition. The baseline anxiety scores obtained for the various conditions for both males and females were well within normal range (6), and there were no significant differences between male (range, 32.5–34.1) and female (range, 34.9–36.9) subjects.

An analysis of variance obtained for anxiety change scores revealed a significant main effect for alcohol dosage level, $F(3,54)=3.59$, $p<.05$. Mean anxiety change scores were −.90, .75, 4.75, and 5.55 for the placebo, 0.5, 0.8, and 1.2 alcohol dose levels, respectively (see figure 1). As determined by a Duncan multiple-range test, no mean was significantly different at the .05 level from that of the next lower or higher alcohol dosage level. There were no significant sex differences with respect to changes in anxiety level across the four alcohol conditions.

FIGURE 1
Relationship Between Alcohol Dose and Change in State Anxiety Score

A comparison of anxiety change scores for the a.m. and p.m. administrations of 0.8 g/kg alcohol dosage by a two-tailed t test revealed no significant effects due to circadian rhythm.

Pearson product-moment correlation coefficients were computed between anxiety change scores and subjects' ratings of their performance following each session and between anxiety change scores and one measure of actual test performance, i.e., on the visual vigilance task, the task most proximal to the second administration of the anxiety inventory. The correlation between anxiety change and perceived level of impairment was $r=.32$ for all subjects ($p<.01$), $r=.06$ for females (n.s.), and $r=.51$ for males ($p<.002$). The correlation between anxiety change and actual performance on the vigilance task ranged from $r=.01$ to .09 and was nonsignificant in all cases.

DISCUSSION

The results of the present study demonstrate clearly a positive relationship between alcohol ingestion and an increase in self-reported state anxiety in a laboratory task-performance situation. This relationship appears to hold for both male and female subjects and to some extent (i.e., with males) seems to be related to the subjects' perceptions of their performance on a battery of complex psychomotor tests. However, whether the fact that one believes he or she is doing

poorly (i.e., rates his or her performance as "impaired") generates anxiety or whether the rise in anxiety serves as a basis for believing that one's performance is impaired cannot be determined by this study. Actual test performance, on the other hand, was unrelated to changes in anxiety level, i.e., how the subject thinks he or she is doing under the influence of alcohol is related more to mood state than to how he or she is actually doing.

Such findings support previous work which has seriously questioned the traditional notion that alcohol is an anxiety-reducing agent (1–5) and with these studies suggest a further examination of the distinction between social drinking, where alcohol may in fact serve to reduce social anxiety and tension, and chronic alcohol abuse (alcoholism), where a vicious cycle of anxiety-alcohol consumption-impaired performance-anxiety may be operating. Our findings further confirm the relationship between the amount of alcohol consumed and the severity of anxiety in evidence (2, 3). They also extend the alcohol-anxiety relationship to female subjects and to nonalcoholic drinkers. In the latter case, these findings do not support Nathan and O'Brien (4), who found no change in anxiety for nonalcoholics in an experimental drinking situation. However, their study examined drinking beh alcoholics from the skid-row area of whereas our study used college student subjects. Thus, the different findings may flect differences in the two study populat

Phencyclidine-Induced Psychosis

BY R. MICHAEL ALLEN, M.D., AND STEVEN J. YOUNG, M.D.

During a 13-month period, 9 patients with phencyclidine-induced psychosis were admitted to Darnall Army Hospital. They exhibited hostility, agitation, and tangentiality and had delusions of influence and religious grandiosity. Six subjects reported auditory hallucinations, and 4 were disoriented in at least 1 sphere. Despite treatment with antipsychotic medication, the psychotic episodes often persisted for more than 30 days. Our clinical finding of prolonged psychotic reactions, together with previous reports of the effects of phencyclidine, suggests that phencyclidine provides an intriguing drug model for schizophrenia.

IN THE FALL of 1975, psychiatrists at Fort Hood, Texas, saw several cases of acute psychosis precipitated by "snorting" or intravenous injection of a whitish powder sold under the guise of tetrahyd (THC). When analysis of samples of this two different suppliers showed them to centrated phencyclidine (PCP), we bega the psychosis associated with phencyclid ingestion, or inhalation.

PATIENT SAMPLE

We reviewed the charts of all patien from Darnall Army Hospital, Fort Hood.

At the time this work was done, Dr. Allen was Chie was Staff Psychiatrist, Department of Psychiatry U.S. Army Medical Corps, Fort Hood, Tex. Dr. sistant Professor of Psychiatry, Texas Tech Univer ademic Health Center, 4800 Alberta, El Paso, Tex is now Assistant Professor, Department of Psyc State University, East Lansing, Mich., and is in pr Kalamazoo, Mich.

a diagnosis of drug-induced psychosis from July 1, 1975, to May 31, 1976. We also included additional patients admitted in June and July 1976. We selected cases if the patient developed an acute psychosis after "snorting," swallowing, or injecting a white or yellowish-white powder believed by the patient to be THC and descriptively matching two separate samples that were reported to be high grade phencyclidine by the toxicology laboratory of Brooke Army Medical Center.

Patients were selected for study only if they had no previous psychiatric history and had a satisfactory premorbid adjustment.

Our patient population did not include the numerous drug intoxications of very short duration (3–6 hours) handled by the alcohol and drug treatment program. Our study group represented only 25%–30% of the phencyclidine-intoxicated patients referred to the psychiatric service, the majority of whom were discharged within 24 hours. Thus, our sample of prolonged phencyclidine-induced psychoses probably represented less than 5% of case contacts by all of the helping agencies on the post.

Nine patients with acute psychosis attributable to phencyclidine were hospitalized at Darnall Army Hospital during the 13-month study period. We excluded 5 additional patients because they ingested other psychoactive substances (alcohol, amphetamine, LSD, and cocaine); however, their symptomatology suggested that phencyclidine was the agent responsible for their psychosis. The 9 subjects in the study included 8 men and 1 woman, aged 18 to 24. Most had a history of multiple drug abuse, but none gave a history of a prior psychotic episode. Specific signs and symptoms of the case material are presented in table 1.

Characteristically, the patients were agitated and hostile and exhibited tangentiality and circumstantiality. They were preoccupied with religious and sexual topics. Seven of the 9 subjects had delusional ideas, predominantly religious grandiosity ("I am Jesus Christ") and delusions of influence (e.g., being controlled by voodoo). Hallucinations were common, with 6 patients reporting auditory hallucinations. One-third of the group was considered suicidal, and 4 were disoriented in at least one sphere. We did not observe the neurological abnormalities reported by other authors, presumably because hours or days had elapsed from ingestion to hospitalization and neurologic examination.

TABLE 1
Presence of Psychopathological Findings in 9 Cases of Phencyclidine-Induced Psychosis

RESPONSE TO TREATMENT

All the subjects were treated with antipsychotic drugs, chiefly haloperidol. Only patients 1, 5, 7, and 9 made a full recovery and remained free of psychotic symptoms off medication at follow-up, which varied from 6 weeks to 6 months after discharge. One week after discharge, patient 2 was readmitted with a recurrence of his symptoms after having stopped taking haloperidol and begun ingesting PCP again. His symptoms gradually cleared in 18 days on haloperidol, and treatment with depot fluphenazine was begun as a preventive measure.

Patient 3 showed no improvement after 3 weeks despite taking 800 mg of chlorpromazine and 30 mg of haloperidol daily. She was then referred to a private hospital where her psychosis cleared with 7 electroconvulsive treatments. After release from the hospital the patient took "acid" and was readmitted, according to the private hospital summary, "psychotic and bizarre," a week later. Again she responded to ECT but remained withdrawn and blunted in affect a month after the last treatment.

Three months after his initial admission, patient 4 improved on thiothixene. However, he had not recovered sufficiently to return to duty and received a medical discharge from the Army. Patient 6 still had loose associations, visual hallucinations, and formication one month after admission, despite receiving 20 mg haloperidol per day. Although patient 8's toxic psy-

chosis seemed to clear completely, he developed a depressive schizo-affective psychosis 1 month later when placed in confinement for legal problems.

In summary, the patients who recovered did so gradually. The duration of their psychotic episodes ranged from 6 days to over 90 days in one patient who had still not improved at the end of the study period. Treatment with antipsychotic drugs was generally ineffective. (One patient responded to ECT.) Treatment by sensory deprivation or benign neglect, although mentioned in several articles (1, 2), was rarely helpful to our subjects.

DISCUSSION

Phencyclidine (phencyclohexyl piperidine, PCP) was developed as an intravenous anesthetic and is still used for that purpose in veterinary medicine under the trade name Sernyl. It produces excellent analgesia without respiratory or circulatory depression (3), but patients given the drug may exhibit agitation and bizarre behavior in the postoperative period (4).

Luby and associates (5) and Davies and Beech (6) observed a consistent syndrome of neurological and psychological changes in normal subjects given .075 to .1 mg/kg of phencyclidine intravenously. The neurological changes included nystagmus, ataxia, and diminished pain, touch, and position sense. The first psychological symptom to appear after drug administration was a distortion of body image, followed by feelings of estrangement, disorganization of thought including tangentiality and blocking, hostility and negativism, and, finally, apathy. One subject became "catatonic" (awake but unresponsive to questions) for 23 minutes (6). All these acute symptoms subsided within 1½ hours. Four chronic schizophrenic patients given the same dose of PCP showed similar responses, with worsening of their thought disorder, increased affect, sexual acting out, and hostility that persisted for 6 weeks (5).

Phencyclidine has been shown to be a constituent of street drugs in 14%–50% of samples analyzed (7, 8). Hart and associates (7) found that 10 of 11 samples of putative THC submitted to various agencies in Lawrence, Kans., contained phencyclidine as the only psychoactive agent. PCP is also commonly sold as mescaline, psilocybin, cocaine, or angel dust. Contributing to the prevalence of PCP in the drug culture is the ease with which it can be synthesized in illicit laboratories.

Rainey and Crowder (1) reported 3 cases of schizophreniform psychosis precipitated by street drugs sold as PCP, THC, and methadone but all believed to be phencyclidine. All 3 of their patients were agitated, uncooperative, and disoriented to place and date. Two of them had auditory hallucinations. When the psychoses cleared in 2 to 4 weeks, all 3 patients had amnesia for the episode. A single patient described by Stein (2) displayed similar symptoms for 10 days but retained partial recall for the episode.

Psychological and motor test data fr... studies indicate that PCP mimics the p... toms of schizophrenia after the acute ... have subsided (9–11). Our experience con... observations. Our patients' reactions to p... resembled the effects of PCP on chronic ... ics (3) in duration and symptomatology. ... our subjects were hyperreligious, delusio... nating, and often disoriented. Thus, in our ... perience phencyclidine psychosis often ... acute schizophrenia. When the Psychotherapist Is Black

BY JESSE O. CAVENAR, JR., M.D., AND JEAN G. SPAULDING, M.D.

The authors present a case report of a white neurotic man treated in long-term psychoanalytic therapy by a black woman psychiatrist. The defense mechanism of reversal—the therapist was white in the patient's early dreams—was evident not only in this patient but in several other white patients treated by the black therapist. The authors suggest that, contrary to the opinions of a few other authors, the reality issues of racial differences can be dealt with successfully in this kind of interracial psychotherapy.

THE LITERATURE on psychoanalysis and psychotherapy when the therapist is black and the patient is white is very meager. There are markedly divided opinions as to the effect this variable may have on the treatment process.

Oberndorf (1) suggested that interracial therapy cannot be effective due to the psychological biases that are present and implied that such treatment should not be attempted. However, Schachter and Butts (2) stated that racial differences "may have a catalytic effect upon the analytic process and lead to a more rapid unfolding of core problems." Other reports in the literature, such as those of Bernard (3), Calnek (4), Grier (5), Kennedy (6), and Waite (7), fall between these two extremes.

Fischer (8) stated that "racial differences between analyst and patient involve issues of unconscious meaning at many levels. These issues and meanings must be recognized and utilized, for there are serious hazards in either overestimating or in ignoring them." Fischer further suggested that the black-white difference is a visible structure on which infantile fantasies may be projected. He concluded that "to ignore the manifest black-white issue is to avoid a piece of the patient's and therapist's everyday reality. To become overly invested in this apparent interracial content, however, represents an effort to deny and negate the deeper intrapsychic conflicts."

Curry (9) suggested that there are important differences in the transference, resistance, and working-through process when the therapist is black. He referred to a complex set of issues he termed "pre-transference." This pre-transference is due to the fact that the therapist does in reality have a characteristic that can mobilize unconscious fears and fantasies, i.e., black color. These fears and fantasies may be unrelated to the individual's past life and are therefore not transference phenomena per se. Curry suggested, as have other authors, that "black" may unconsciously represent bad, evil, darkness, and inferiority. These same fears may be represented in mythology by Satan, Lucifer, or Judas.

Curry implied that this pre-transference reaction may be used as an effective resistance to the formation of a transference. When the racial issue becomes a point of attack on the therapist, it is because of these unconscious fantasies and the anxiety generated by the fantasies. Curry concluded that if the patient's own conflicts become interlaced with "the patient's hypercathexis of a reality situation," i.e., the therapist's blackness, an insurmountable resistance may form that precludes treatment and leads to acting out. Effective interracial psychotherapy is thus possible only if proper attention is directed to these complex pre-transference, transference, and resistance issues.

We became interested in this racial variable in long-term psychoanalytic psychotherapy involving white male patients and a black female psychiatrist. We were also curious as to whether dream productions would be affected by the racial differences.

It has long been a clinical observation in psychotherapy and psychoanalysis that the patient's dreams frequently disguise a white therapist as a black person. This is most commonly noted in the early and middle phases of treatment as a defensive maneuver and usually ceases as the patient's defenses are lowered. Altman (10) reported a dream in which a white analyst was disguised as a black person via condensation, displacement, and symbolization. We wondered whether the same defensive maneuvers would apply when the therapist is black; that is, would the black therapist be represented as white in an attempt to disguise transference feelings?

The purpose of this paper is to report a case of a white male neurotic patient treated by a black female therapist in which these variables of interracial treatment and dream productions could be studied in detail. This case is representative of several long-term patients treated under similar conditions; all cases illustrated the same principles.

CASE REPORT

The patient was a 25-year-old single man who came for psychiatric evaluation because of marked free-floating anxiety, multiple phobias, and an inability to urinate in public places. He had been born and raised in a small southern town; his parents were from the middle class. He was the second of a set of nonfraternal twins and had one sister who was two years older. He described his father as a sadistic, angry man who was emotionally distant from the children and his mother as a seductive woman who frequently walked around the house and yard nude in view of the children. She bathed the patient until he was in early adolescence. When the patient was 13 years old his mother and father separated briefly. The mother took only the patient with her when she left; he slept with her until they returned home. The father accused the patient of having seduced his mother, and his inability to urinate in public places dated from that experience.

We felt that the patient had an obsessive-compulsive personality with hysterical and phobic features. His main defenses were isolation of affect, reaction formations, repression, and displacement. Psychoanalytic psychotherapy was judged the treatment of choice.

The patient presented his first dream in hour 6. His early feelings about the therapist were well disguised by condensation, displacement, and symbolization. He reported, "The dream occurred at a place I had never been before. It seemed to be a church and I went to a classroom with 15 other people. I knew no one: it was a class on vectors. There was a girl to my left, two seats down from me; she looked over and smiled. It made me feel good, and I had a sense of well-being. After the class I walked by a restroom, and I knew I could go in and urinate without any tension." The girl in the dream was white.

The strongly erotic nature of the evolving transference was indicated in a dream reported in the 10t... on the campus of the university for a summe... go to the athletic field for the field trip; one b... are girls, and a woman instructor is there. I f... the field trip; after the class broke up, the ... gested to me that we have a separate meeting ... denly I didn't want to be there; I became c... urination. I've looked for things about black people t... about. If one did something that I felt was im... generalize to all black people. I don't like the ... don't like myself, I guess."

As the projections by the patient were gr... through, it became clear to him that he actu... downtrodden, oppressed, and in other ways ... perceptions of blacks. This phase of the tre...

illustrated by the following dream, reported in the 74th treatment hour: "I went to this black woman's house. It was you. A picture of your mother was there. I thought, 'Her mother does look black after all.' Then my mother, father, brother, and I were sitting around a table. It was as though we were more black than white."

Over the following 18 months, an intense erotic transference neurosis developed. This transference neurosis was worked through as any other would be; no alteration of technique was made necessary by the racial differences. The patient experienced good symptomatic relief of his phobias and urinary problem and a marked lessening of his anxiety. He began to date girls for the first time in his life, his relationships with both black and white authority figures and peers improved, and he began to take several courses to further his education.

At the end of 3 years of therapy, the patient began to bring typical termination dreams. One such dream was the following: "I was standing on an island and the water began to rise. I needed shelter, so I went to a nuclear fallout shelter. You were there with a group of people. I needed to urinate, but there was a man occupying the bathroom. I needed to go and find my own bathroom. I went into the woods to urinate: I wasn't uptight at all. I saw a woman in the distance, and I knew I could talk with her." We felt that this dream was like those presented by Oremland (11) in which the therapist, undisguised, is involved with an initial symptom that brought the patient to treatment. The dream appears to indicate resolution of these symptoms. This patient's psychotherapy went on to a successful conclusion several months later; no additional resistance was encountered.

COMMENT

The case reported here is one of several long-term psychoanalytic psychotherapy cases we have experienced in which the therapist was black and the patient was white. We believe that interracial psychotherapy can be as productive as any other psychotherapy. Certain different features must be recognized and dealt with accordingly.

The dreams of a white patient will be different in that the black therapist may be disguised as white. The defense mechanism involved is reversal, and it appears to work in the identical manner as when the therapist is white and disguised as black. Clearly it is an attempt of the dream work to deal with anxiety. In our experience, it is common for reversal to occur in dreams; in fact, we would be concerned about the integrity of ego functioning if it did not occur. In our patients this reversal has continued to appear in dreams until a sufficient number of the conflicts have been worked through to permit the therapist to appear undisguised in dreams. A transference of sufficient intensity must also have formed; in the absence of this transference there would be little intrapsychic reason to cathect the therapist sufficiently to dream of him or her.

In our experience, the dreams in which the black therapist was disguised as white revealed little overt anxiety. When the reversal disappears as a defense mechanism and blacks first appear undisguised in dreams, overt anxiety is most often present. In the dreams this anxiety may be noted in the manifest content by the blacks being large, hostile, threatening, or even murderous. Whether the anxiety is greater than in the usual situation, when the white therapist is dreamed of as black, we cannot say with any degree of certainty. Our impression, however, is that the anxiety in the patients we treated was greater.

Another common finding when the therapist is black is the tendency of the white patient to overidentify with the therapist's blackness. All of the patients whom we have treated have done this to some degree; it is our impression that patients who have low self-esteem, are passive, and feel oppressed and constricted intrapsychically overidentify more readily with the black therapist.

The overidentification with the black therapist may have many meanings. Most often, in our experience, it is a hostile identification, a way of appearing compliant and complacent but expressing hostility. In some patients, what appears to be an overidentification is not an identification at all but a massive projection of the patient's unconscious conflicts. The patient merely identifies with what he or she believes the black therapist's plight or station to be, when in fact it is totally distorted.

Although the same conflicts must be worked through in this kind of interracial therapy as in any other treatment, the sequence of the unfolding of the conflicts may be altered by racial issues. The differences in race may serve as a scaffold for multiple projections by the patient. Projections pertaining to race must be dealt with early in the treatment by helping the patient to appreciate that these are unconscious conflicts that the patient is experiencing. Our experience suggests that once this is accomplished the transference neurosis will develop as it does in any other treatment process and the patient can proceed to a satisfactory working through and termination. Although other authors have reported that the reality issues of racial differences cannot be adequately dealt with in some patients, we suggest from our experience that this is not the case.

Psychiatric Training for the Primary Care Obstetrician-Gynecologist Resident

BY PRISCILLA DAY BOEKELHEIDE, M.D.

The author describes a model for the psychiatric training of obstetrics-gynecology house staff members who serve as primary care physicians for women. By integrating psychiatric skills with specialty training, the psychiatrist can enhance continuity of patient care for the resident during his transition to the role of primary care obstetrician-gynecologist.

WELL BEFORE THE 1975 position statement by the American College of Obstetricians and Gynecologists and the American Board of Obstetrics and Gynecology on the role of the obstetrician-gynecologist in the primary care of women (1), I was invited to share a woman's point of view with the obstetrics and gynecology house staff of a large inner city nonprofit hospital who viewed themselves as total physicians offering comprehensive continuity of care to women. The house officers already recognized that they were often the first medical contact for their patients, that their responsibility should not be limited to acute illness, and that normative life crises required diverse skills such as marital, pregnancy, and sexual counseling, menopausal care, and supportive therapy for the cancer patient. The keys to their development as primary care physicians were their eagerness to learn and to accept the role and the use of a peer collaborative psychiatric consultant on their team.

In addition to the senior psychiatric consultant, the house staff included a teaching-atten three residents, two interns, and one students. No grant or special exter tributed to the program, and most obst cology teaching situations could re shaped toward the same goals. My acce program was probably enhanced by m a fellow resident but also a Fellow o College of Obstetricians and Gynecol

knowledge such as legal involvement was required, direct consultation with the patient was available. Occasionally there were conflicting opinions, e.g., between traditional medical/surgical and psychiatric opinions about a hysterectomy.

CLINICAL VIGNETTES

Some examples that typify primary care throughout the life cycle follow:

1. A young father brought his newborn for a circumcision check. His anxiety offered the intern an opportunity to discuss his feelings as a new father and as a recently neglected (as he saw it) sexual partner.
2. A mother brought her 10-year-old pubescent daughter to check her vaginal discharge, asking covertly for sex education help.
3. A grandmother accompanied her pregnant, unmarried adolescent granddaughter. Social issues of abortion, placement, and illegitimacy were discussed.
4. A young, single, nulliparous, feminist insisted on a hysterectomy, challenging the house officers' value systems.

In addition, the overburdened abusing mother and the frankly psychotic pregnant woman required application of learned medical skills as well as the peer consultant's specialized viewpoint to meet the patients' psychosocial-medical needs. The aim was to keep the personal physician involved as much as possible, encouraging him/her to participate by using interviewing, diagnostic, and treatment skills as needed for brief supportive psychotherapy, Masters and Johnson's or Seman's techniques, etc.

RESULTS

As the house staff reported progress with their patients, they were encouraged to be more flexible in having patients return according to psychological needs; e.g., the postpartum patient who was depressed was seen briefly but frequently rather than for the usual one visit at four to six weeks. The staff learned quickly to focus on the emotional problem, not necessarily the presenting obstetrics or gynecology problem. As a result, some important changes occurred:

1. Labeling of patients changed from "that hysteric" to "Mrs. A," and family dynamics were examined.
2. In selected instances various social services, the pediatrics department, or the occupational therapy section helped in the functioning of the obstetrics-gynecology service and hence in training of its staff.
3. Interdepartmental practices were examined for therapeutic interaction.
4. "Nuisance" calls from patients declined dramatically as the house officers learned to meet dependency needs more directly in the clinics.
5. More appropriate referrals for psychiatric consultation were made, reflecting a focus on prophylaxis and preventive care.
6. Staff time with patients became more productive and the house officers became conditioned gradually to what Burnham (4) calls "practice shock," i.e., the pleasure of treating all types of patients instead of only the unusual, esoteric, or very difficult.
7. The usual clinic diagnostic categories such as toxemia, unwanted pregnancy, and imperforate hymen were redefined to include such concepts as anxiety, dependency, ambivalence, and nonconsummation of marriage.
8. Problem orientation broadened to include the patient's family, body image, and sexual identity.

DISCUSSION

Many demands are placed on the obstetrician-gynecologist when he/she changes from the omniscient and omnipotent authoritarian figure and becomes a true participant in primary health care delivery and service for a large segment of the population. As the primary care physician for women he/she must be prepared to offer periodic comprehensive evaluation of their health status, which includes health education, preventive care, health maintenance, referral to and integration of other health services, and traditional therapeutic services throughout the life cycle of his/her female patients.

Sound psychiatric interventions, once thought to interfere with the busy clinician's schedule, can be integrated into the usual 10- to 20-minute patient visit. This addition makes clinical orientation a more relevant experience for both patient and physician. Through teaching and example during the residency years the psychiatrist can aid this transition from obstetrician-gynecologist to primary care physician.

Psychiatric Consultation in an HMO: A Model for Educatio Primary Care

BY LOUIS F. RITTELMEYER, JR., M.D., AND WILLIAM E. FLYNN, M.D.

The authors describe a program based on a biopsychosocial model of illness, which uses a liaison-consultation approach in an outpatient setting. It is directed toward integrating psychiatric education and services with primary care in a health maintenance organization. This program can serve as a useful model for studying the validity and effectiveness of integrating psychiatric concepts with primary health care.

PSYCHIATRY'S INVOLVEMENT with the education of primary physicians has gone through an evolutionary process since its inception about 30 years ago. Stimulated by the need for psychiatric manpower during World War II, it has developed into organized programs for medical students, practicing physicians, and residents in other fields, principally family medicine (1, 2).

For four years the Georgetown University Department of Psychiatry has provided psychiatric educational and clinical services for a university-sponsored health maintenance organization (HMO). In this paper, we will focus on two aspects of this experience: 1) the conceptual model used in designing and carrying out the psychiatrists' roles and responsibilities; and 2) the methods employed in the educational programs for primary care physicians and nurse practitioners and for psychiatry residents assigned to provide services to the Georgetown University Community Health Plan (GUCHP).

THE SETTING

When the program for GUCHP was begun in July 1974, there were two centers providing patient care—one in an inner-city neighborhood in the northeast part of Washington, D.C., the other in a "new town" in Virginia, located more than 20 miles from the Georgetown University Medical Center. The been in operation for about 1½ years. ture of fee-for-service patients and erro paid plan. The psychiatric program applies a liaison-consultation approach in an outpatient setting. It uses current concepts of psychosomatic medicine, as described by Lipowski (3), to help primary physicians in "assessing the relative contribution of psychological, biological, and social factors to the development, course, and outcome of physical and psychiatric disorders." The consultant supports the primary practitioners in caring for even their most troublesome patients, i.e., the anxious, depressed, angry, and hypochondriacal. He/she functions as "an integral component of the general health care structure rather than a separate [mental health] service," a role similar to the one defined for psychiatrists in the New Haven HMO (4).

This approach derives from a belief in what is now termed a biopsychosocial model, which has been described in detail by Engel, who summarizes its essence clearly: "To provide a basis for understanding the determinants of disease and arriving at rational treatments and patterns of health care, a medical model must also take into account the patient, the social context in which he lives, and the complementary system devised by society to deal with the disruptive effects of illness, that is, the physician role and the health care system" (5, p. 132).

METHOD

Instruction of primary physicians and nurses is similar in most respects to that used in continuing education and in family practice residency programs here (2, 6) and elsewhere (7–9). Regularly scheduled consultations, with a case-oriented focus, provide the basic framework. In addition to discussions of individual patients and families, patients are interviewed and selected articles are reviewed.The referring physician is present when the consultant interviews a patient; this emphasizes the consultant's role as a teacher.

During consultations, which are held at least once weekly in each center and last 20–30 minutes, primary practitioners meet with the consultant to discuss new patients and those who need follow-up by the primary practitioner. In the course of a typical three-hour consultation, 6 to 10 practitioners (and occasionally administrative personnel) are consulted with, individually or as patient-care teams. These are working sessions in which decisions on patient management and disposition are made and the psychiatric social worker participates.

The tone of the conferences is informal. One physician might use several brief anecdotes to obtain the consultant's help in understanding a problem; another might give a detailed case history. There is an open-door policy allowing staff members to enter and leave without disturbing the flow of discussion and permitting all to learn from the experiences of each one. There is also an atmosphere of goal-directedness. Everyone present is interested in working on patient-care problems. Even when discussions focus on staff issues, the objective remains that of better serving patients.

Another feature of the sessions, most apparent in the center located in the "new town," is the mutual value placed on the time spent together. The physicians coined a term, "psych time," to designate the period that each of them meets with the consultant. This time is jealously protected, and patient appointments are seldom allowed to intrude on it. This attitude developed slowly, but over a two-year period became a part of the center's subculture. Now it so pervades the center that newcomers are expected to fit into the routine, and most have little difficulty doing so.

Cases presented to the psychiatrist lead to recommendations that follow one of three general patterns: 1) suggestions for continuing evaluation or care by the primary care team; 2) further evaluation by the social worker or resident; or 3) referral for treatment by one of the mental health professionals. Acceptance of patients for psychiatric evaluation or treatment does not end the patient's relationship with the primary care team, which continues to render other necessary care.

Training is also provided for psychiatry residents; it is intended to meet the increasing demand for collaboration between psychiatrists and primary physicians. This training is designed to facilitate the integration of psychiatric services in an HMO, which requires a different orientation and additional skills that often are not emphasized in other training settings (10).

Residents are assigned to the centers in six-month rotations. Their training is centered around case consultation and brief outpatient therapy (the limit on visits provided under the prepaid plan is 20 per year). The residents' work is supervised by the consultant.

CASE REPORTS

The kinds of problems addressed run the gamut of those seen in a busy ambulatory practice: anxiety, depression, marital conflict, alcoholism, emotional disturbances of children and adolescents, and a variety of diagnostic and management problems with chronically ill patients. How some are dealt with can be seen in these examples.

Case 1. A 49-year-old divorced woman complained of severe pain in her feet. Although this symptom had existed for only a few weeks, she had a history of multiple complaints, difficult interpersonal relationships, and an inconsistent work record. A thorough workup, including consultation with two orthopedic surgeons, failed to establish a diagnosis of any pathology. Treatment had consisted of numerous medications to relieve pain, none of which was effective.

The consultant considered this to be a case of hypochondriasis and recommended a supportive regimen consisting chiefly of regularly scheduled visits to the center, with the care-giver offering his time (usually 15 minutes), attention, suggestions for reestablishing relationships with friends and nearby family members, and encouragement to regain her

functional ability to work more productively. Initially she was seen weekly, later biweekly. The consultant's involvement continued for about three months, when the practitioner, a physician's assistant, had the confidence to carry on without further help.

Case 2. A 5-year-old girl had recently begun soiling herself following the birth of her only sibling. The pediatrician was prepared to deal with the child's reaction to her new sibling, but the parents insisted on a more detailed organic workup. It further developed that these parents had acted similarly in another health crisis (involving care of the newborn), and the physician expressed disappointment that the family had not learned from that experience. The consultation focused on the dynamics of the parents' need to urge further testing. The physician found it helpful to identify and understand the pattern of the parents' behavior and to be supportive in his dealings with them.

The model for this approach has been described by Kahana and Bibring (11). It is used extensively in helping the primary practitioners develop an approach to their more difficult patients.

Case 3. A physician's assistant presented the case of an alcoholic woman who made repeated demands for minor tranquilizers but refused treatment for her alcoholism. The consultant offered the assistant some basic information about alcoholism, Alcoholics Anonymous, and the use of disulfiram (Antabuse).

One month later the patient had not attempted to stop drinking, but she was not demanding tranquilizers and was considering a visit to A.A. The physician's assistant was encouraged to go to an A.A. meeting himself so that he could discuss A.A. more knowledgably with the patient. Subsequently, the patient stopped drinking and began attending A.A. meetings. The likelihood of relapses was discussed, and the practitioner continued to follow the patient with a more comfortable sense of the role he could play in the woman's care.

Case 4. An internist presented the case of a 32-year-old woman who wanted to see him for counseling on a regular basis. She had undergone intensive psychotherapy previously but felt she had not received much help and wanted to try again with this physician. The patient's wishes and expectations were discussed with the psychiatric consultant, which helped the physician realize the unreality of her request. He was able to be supportive to the patient and at the same time set clear limits as to his availability for counseling.

COMMENT

We believe that this program is integrative in two important respects: 1) it combines psychiatric in-service training and consultation for primary practitioners with the service responsibilities of the health center; and 2) it integrates psychiatric services and the training of psychiatry residents with the general health care offered in an HMO.

For this integrative effort to be effective, the consulting psychiatrist and the social worker play key roles. The psychiatrist must have a conviction that the assumptions on which the program is based are valid, and he must be prepared to demonstrate its usefulness to skeptical and, at times, reluctant primary physicians. The social worker must possess the organizational and interpersonal skills to coordinate psychiatric patient-care and educational activities as an integral part of primary care services.

Our experience has borne out the assumptions with which we began the program. It is clear that primary physicians can function well in giving comprehensive care to patients, including many patients with emotional problems. These physicians require inservice training and consultation on a continuing basis and in most instances respond positively when it is offered to them.

At this time, documentation of these conclusions is anecdotal. With more experience and after review of the continuing modifications that will result, a more quantitative assessment will be possible. For the present, it is enough to know that the assumptions appear to be valid and further assessment of them is justified. We can draw some tentative conclusions about the differences between this kind of program in an HMO and a similar one offered to physicians in fee-for-service practice. The receptivity of the physicians is significantly greater than when postgraduate seminars were offered to practitioners in the Washington, D.C., area several years ago (2). In contrast to the fewer than 5% of physicians in general who avail themselves of such continuing education opportunities, those in the HMO actively participate with few exceptions. (Regular attendance—i.e., at least every other week—varies from virtually 100% in one center to more than 50% in the other two.)

Several factors must be considered in understanding this response. The consultations are convenient, i.e., they are conducted in the center itself, and no travel is involved. In addition, there is no personal financial sacrifice by the physicians to participate; it is considered part of his working day. Another factor that also appears to play a part is the limited options for both patients and physicians to "shop" when one or the other encounters difficulty in the doctor-patient relationship. Patients have only three or four choices of primary physicians; the physicians are obliged by the HMO contract to provide services to enrolled patients. This limits the physicians' ability to avoid unpleasant patients, and consultation becomes a way of dealing with such patients more effectively and with less frustration.

We believe that the consultation approach taken by the psychiatrist is crucial and that the liaison-consultation model described has been significant in making the program work. Two experiences in GHCHP support this belief.

Before the initiation of this program, a part-time psychiatrist provided consultation in a traditional manner for 1½ years. Neither he nor the social worker was ever fully integrated into the functioning of the centers, there were fewer diagnoses of psychiatric prob-

lems, and little attention was paid to management of emotional disorders by most of the primary physicians.

In one of the centers, the liaison-consultation approach was abandoned temporarily (for reasons beyond our control). During that time and for many months after, integration of services and a collaborative approach to patient care were difficult to achieve. This was true despite the center medical director's concurrence in our approach and his own skillful use of it in caring for his patients.

Finally, the psychiatric consultants' administrative role is significant. Decisions on patient care are made jointly, with primary physician, social worker, and consultant each contributing his own expertise. Referral to a mental health professional is seldom made without the consultant's concurrence, and responsibility for ongoing care is always shared, regardless of who provides the psychotherapy. Because of the consultant's continuing involvement, the primary physician more readily accepts the principal psychotherapeutic role.

Success or Failure: Psychotherapeutic Considerations for Women in Conflict

BY CAROL C. NADELSON, M.D., MALKAH T. NOTMAN, M.D., AND MONA B. BENNETT, M.D.

The authors describe conflicts experienced by women who request therapeutic intervention because of symptoms of depression, anxiety, marital discord, difficulty in asserting themselves, or inability to complete work that would lead to advancement. They discuss the developmentally based difficulties experienced by women in making career choices, advancing their careers, and facing midlife issues. The therapist who deals with such patients must be aware of reality-based factors and of his or her own values and attitudes as they influence choice of therapeutic approach.

AMONG THE MANY CHANGES of the past decade has been an increase in the number of women entering professional careers. Establishing a professional identity is a more complex and difficult problem for women than for men (1) because self-actualization, the pursuit of independent goals, and risk-taking have not been seen by our society as consistent with "femininity." Women are often conflicted about activities regarded as aggressive or competitive because they fear loss of approval and rejection if they violate established norms.

Until recently, women entering careers thereby chose a life pattern that set them apart from most of their peers. The capacity to tolerate being "deviant" has important psychological implications. Psychotherapists see women who are successful in many areas but who are conflicted about the discrepancy be-

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

tween their aspirations and activities and their early familial and developmental experiences. Therapists are influenced by the same cultural, familial, and intrapsychic factors as are their patients. Thus, they may find it difficult to objectively examine the nature and intensity of the conflicts presented. For every therapist the ability to differentiate what is actually mentally healthy from the idea of what is healthy according to subjective personal values becomes critical. This differentiation is more complicated than is often acknowledged, and the problem is made more acute by the rapidity of change in values and mores in recent years.

Concepts of what is healthy as well as what is appropriate, rational, or acceptable clearly differ among individuals; objective criteria are not available. In 1970 Broverman and associates (2) demonstrated that views of mental health are affected by sex role stereotypes. Although some changes have occurred since their study, the personal and cultural values that enter into therapeutic decisions continue to be particularly salient in the treatment of women.

Biological and reproductive factors are also inevitably important in any discussion of therapy of women. Although these factors clearly do not constitute a woman's identity, women's lives are more influenced by their biological timetables than are men's lives. All women are concerned in one way or another about this reality from the beginning of adolescence. Although men are concerned about fertility, they do not organize their life plans around reproductive issues in the same way women do. Thus, considerations of goals and values as well as of the developmental life cycle and reproductive issues provide a framework for understanding the problems currently presented by women in therapy.

CAREER CHOICE

Early in life one often makes choices on the basis of idealism, romanticism, faddism, or family pressure without adequate appreciation of the complexities and realities inherent in any choice. The rapid increase in the acceptability of and even insistence on women's achievement has found many women unprepared for making these decisions or for following through on decisions already made. This is particularly true for young women whose early developmental experiences were in families with a traditional orientation. The past identifications of such women may not provide models for future expectations. Anxiety may occur when a young women attempts a life course that she believes would either exceed her mother's achievements or meet with disapproval, particularly from her mother. She may be concerned about expressing aggressive or competitive feelings. In the past a woman might have avoided the entire dilemma, but current expectations, including her mother's, often make that option less feasible today.

CAREER DEVELOPMENT

The transition from student life to actively establishing a career requires a confrontation with pressure that may be quite different from those which were fantasied earlier in life. Women are often poorly prepared to face the demands of a career, perhaps because they have not conceptualized themselves as functioning in this role. They may find themselves unable to make long-range career plans and unconsciously sabotaging the efforts of others to help them. They may regress and become more dependent, helpless, or childlike to gain approval and aid from male colleagues; they may choose jobs that are less interesting and rewarding when confronted with the option of assuming responsibility, or they may deprecate their achievements to avoid jeopardizing relationships with men. Although these behaviors might have been successful for women in some areas, they are generally counterproductive from the perspective of attaining professional goals. Many women seek therapy because of the symptom of depression, anxiety, marital discord, difficulty in asserting themselves, or inability to complete work that would lead to advancement.

Conflict avoidance and regression diminish anxiety by preventing the open expression of ambition or self-assertion. Because acknowledging aggression, even when it is conceptualized in terms of mastery and creativity, is more threatening to women than to men[1] the therapist must be ready to confront resistances to achievement when achievement is perceived as aggression. Because women often view competitive activity as injurious to others, they may feel guilty about competing (3).

Women may become depressed after recognizing anger or discontent with a situation they had previously accepted. This occurs because the woman feels that by experiencing or expressing anger she has violated her internalized ego ideal as a nonaggressive person. She may continue to see herself as helpless and powerless[1] or may retreat out of fear of losing the relationship if she expresses angry feelings. Even "successful" women may maintain this self-image.

The need to avoid conflict leads women to structure their lives so that certain wishes are never tested or fulfilled. Sometimes a life event serves to avoid a confrontation; e.g., an unplanned pregnancy may make it less possible to return to work. At times, conflicts are externalized and projected and/or displaced onto family, bosses, peers, the demands of work or the presence of discrimination. This is particularly complex for a therapist to unravel because there may be considerable reality in the woman's perception of the external difficulties. The therapist must ally himself or herself with the patient in her exploration of her conflict about self-assertion and help her to examine the ways in which she may mask her competent self. It

[1] Miller J, Nadelson C, Notman M, et al: Reconsiderations of aggression and self-esteem in women (unpublished paper, 1977).

important not to simply share her externalizations.

Many women approaching the age of 30 come for treatment when they begin to face the possibility that they may not marry or when they decide not to marry. Even if they have been ambivalent about marriage, the reality of not marrying or of not having children may foster a sense of deviance or defectiveness and lower self-esteem. On the other hand, the peer pressure currently applied toward not having children may make it difficult for some women to face their ambivalence or their sadness about giving up the possibility of having a child. Some women have difficulty taking major professional steps or even making such personal decisions as moving to a better apartment or buying a car at this time. They may fear that these changes would seem to represent a commitment to being unmarried. They may blame their career for their social isolation. Some women find a masochistic solution—they might make choices that avoid serious and potentially rewarding career commitments in order to keep relationship "options" open. They may then become angry and disappointed when rewards do not materialize.

Some women handle these conflicts by adopting a life pattern in which they function as "one of the boys." This may be adaptive because it permits them to be strong and competent peers; it also avoids sexualization of relationships. The cost, however, may be an inability to accept sexual or dependent feelings. These counterdependent mechanisms are often accompanied by rigidity and can interfere with empathy in interpersonal relationships.

Women who attempt to retain their emphasis on relationships without sacrificing the development of competence and assertiveness have a difficult time, particularly in such "masculine" fields as engineering, architecture, and management. They need support and reality testing, and they must also maintain sufficient self-esteem to prevent failure.

Women who combine marriage and a career often experience role strain (4). This may occur early in their careers or at a point when they begin to increase their involvement in activities that do not involve their families. Their husbands may develop a sense of loss and abandonment and may become competitive, demanding, or regressed. Children also often experience such changes as losses. Guilt over these reactions can lead women to give up their outside interests or may stimulate them to overcompensate and become too self-sacrificing. Some women respond by displacing or projecting their anxiety and are thus seen as overcritical, intolerant, or unresponsive. Some women externalize in this situation and see their family as the major source of their problems rather than understanding their own conflicted responses to pressure. Problems with children are especially likely to precipitate guilt and anxiety (5).

At times marital or sexual problems occur. There has been considerable speculation about the possible increase in male impotence as a result of the increase in women's aggressive behavior and sexual demands. Although there is no good evidence to support this idea, the concern evoked reflects men's anxiety about their masculinity when traditional roles are changed, when they receive more demands for sexual performance and for assuming traditionally feminine tasks and roles. Psychological withdrawal, including loss of sexual interest or potency, sometimes rigid conpensatory assertions of masculinity, or other symptoms may occur as attempts to restore self-confidence and diminish anxiety.

The specific problems of the dual-career family are rarely considered before a couple embarks on this path (6). Generally, each partner makes plans and sets individual goals; these might not be consistent with family demands. Problems often appear in dual-career families when children are born. Conflicting demands force confrontations because alteration of schedules and plans are required. In this situation, as with other conflicts, the wife usually is the accommodating person, limiting her goals and expectations (7). She may then seek treatment because of depression, inability to handle anger, marital friction, or problems with children.

A woman returning to a career may find reentry stressful; it is also difficult to increase a time commitment if she has been working part-time. Positions may not be available, the demands of a particular field may have changed, she may not have the credentials to enter at the level she seeks, or she may find herself working with younger and less experienced colleagues. Women are often unable to confront their passivity and their internal restrictions on aggression and its expression when a more active commitment is necessary in the new role they seek. Depression and anxiety may result when they challenge their internalized self-image, or aggression may be mobilized, resulting in guilt feelings. Some women act out and seek their own "space" by leaving their families. Others avoid the challenge by backing down and refusing positions of authority and responsibility, although they often state that they want these positions. At times a woman views her husband or family as critical or unaccepting as a way of dealing with her own ambivalent feelings.

MIDLIFE ISSUES

As people approach midlife they reflect on the choices they have made. Women who have not married or who have not had children may feel they have paid too heavy a price for the choices they made. When underlying anger is mobilized, they may find it difficult to handle it appropriately or productively and may seek treatment. On the other hand, women who have placed family commitments before their careers may face losing their primary source of identity with the onset of menopause. Divorce, the death of a spouse, the fact that children are leaving home may precipitate anxiety, depression, or regressive symptoms. Women with important career investments seem

to be less vulnerable to depression in the midlife years. Those who have not had children have generally come to terms with this before they reach menopause. Women who are heavily invested in family roles respond more strongly to the menopausal changes (8).

THERAPEUTIC IMPLICATIONS

Although many of the issues considered here are clearly applicable to men as well as women, we will emphasize them as they relate to women.

Therapy Referral

Specific requests may be made for male or female therapists by patients or by other therapists. Women therapists are most often chosen for referral of women patients to avoid a sexualized or a potentially difficult authoritarian transference, for the therapist's "maternal" qualities, and/or to provide role models. Women who choose a woman therapist often feel that she would be more responsive to their wishes for self-actualization. The reasons for choosing a therapist may be based on stereotyped or traditional views without regard for the characteristics of the individual therapist (9). Nevertheless, these preferences may be important. The patient's feeling of greater comfort or empathy can facilitate the development of a positive therapeutic alliance.

Reality-Based Factors

The realities of the patient's specific life situation are important factors that influence the choice of therapeutic modality or approach. A method of problem-solving or conflict resolution that is optimal under certain conditions may not be realistic in others. It is obvious that a woman who must decide about continuing or aborting a pregnancy requires a short, focused therapeutic approach rather than long-term therapy. A 40-year-old woman with conflicts about becoming pregnant cannot spend several years in psychoanalysis before deciding whether or not to have a child. Less obvious but important variables are the needs, priorities, and emotional resources relating to a particular situation that may be externally stressful. For example, a woman medical student with problems in her relationships with men might be a good candidate for intensive psychotherapy or psychoanalysis, but while she is in medical school she may benefit more from a therapeutic experience that is less demanding and puts less strain on her academic performance.

Values, Attitudes, and Countertransference Issues

The values and attitudes of the therapist can influence clinical formulation, choice of treatment modality, and even the focus of therapy. For example, because social relatedness is generally considered to be more critical for women than men, a woman with serious problems in interpersonal relationships but who is successful in other areas of her life may find that her therapist is more concerned with her interpersonal relationships than her career-related issues, regardless of the priority the patient assigns to this area. This interpersonal emphasis is more likely to occur with a isolated but occupationally successful woman than with a man. Demands involving work or academic requirements are often treated as resistance in women. Some therapists still regard success for women in traditional terms; such therapists may not take self-actualization related to nonfamily areas of life seriously or may see it as postponable for women. Therapists and patients may limit their exploration of alternatives because they see career and family involvement as mutually exclusive or too complex.

Therapists may also find it difficult to understand women who decide to have children when they are older or who are ambivalent about having children. These therapists may not realistically explore career goals and possibilities or potential problems and pitfalls. The woman house officer who wants to have a baby but who has undertaken a very demanding program may need the opportunity to explore why she chose to become so committed at the particular time she did, just as the 40-year-old woman with an established career who suddenly decides to have a baby and give up her career must understand this decision. Both women may be acting out in a self-destructive fashion or may have important positive reasons for their decisions.

Another area of concern is the therapist's view of what constitutes psychopathology in women. The therapist who finds it difficult to accept aggressive or assertive behavior in women may accept a woman's passive, masochistic stance rather than help her master her anxiety or depression by taking a more active self-directed position. On the other hand, the therapist may pressure the patient into unwanted competitive activity and major career commitment because the therapist feels this is appropriate. Regressive behavior as a defensive style may be seen in a woman as characterologically primitive when it is a style of presentation or a manifestation of low self-esteem not necessarily related to major defects in ego functioning. A supportive rather than explorative therapeutic approach may then be recommended.

Countertransference feelings may lead therapists to overidentify with patients and to project their own experience onto them. They may be in awe of women who are effective professionally and not attend to the concerns they present. The patient herself may support this perception because of her need for control, a quality that is important in her professional success. Thus, both patient and therapist may collude to accept a view that leaves out important areas for therapeutic work. In such instances therapists may foster a more egalitarian or intimate relationship or a more distant one than is helpful to the patient.

The impact of feminist views has led many patients to mistrust formulations that use psychoanalytic language (10) because of the implications of such terms as

penis envy. The therapist or analyst who interprets this as resistance without understanding the patient's concerns will come to a therapeutic impasse. It may be necessary to explain, to avoid jargon, and to specifically reinforce the alliance between individuals rather than ideologies. A stance perceived by the patient as provocative, paternalistic, or authoritarian may make it difficult or impossible for her to develop a trusting relationship.

COMMENT

Feminine identity, reexamined in the light of recent evidence and in the context of social changes, includes the integration of self-esteem, self-assertion, and independence as well as nurturance. A developmentally oriented view of feminine development and conflict supports the view that it differs from male development because of the impact of the reproductive timetable. Both childhood and adult developmental phases must be incorporated into concepts of femininity as a changing process with different expressions at different life stages.

For the professional woman this integration is particularly important. The therapist must be sensitive to problems arising from conflicts between the demands of professional adaptation and internalized contradictory expectations deriving from developmental experience. The therapist must be aware of the impact of real life events as well as intrapsychic conflict in symptom formation. Formulations and therapeutic approaches must be modified in the light of data from a number of disciplines and in the context of social change.

Psychotropic Drugs, Summer Heat and Humidity, and Hyperpyrexia: A Danger Restated

BY STEPHAN C. MANN, M.D., AND WILLIAM P. BOGER, M.D.

The authors note an apparent unawareness of, as well as a paucity of recent literature pertaining to, hyperpyrexia as a complication of psychotropic drug treatment. They report a case of hyperpyrexia in a patient receiving psychotropic agents during a summer heat wave; massive muscle destruction (rhabdomyolysis) with myoglobinuria and acute renal failure make this case of particular interest. Causative mechanisms, preventive measures, and the benefits of prompt recognition and treatment of this condition are discussed.

IN A June 1970 report (1) of heat stroke fatalities among phenothiazine-treated patients, Zelman and Guillan stated, "The phenomenon of hyperpyrexia in phenothiazine therapy is not new, but has been little discussed. . . . We feel it urgent that . . . [our] experience be reported in order that such catastrophes may be anticipated and guarded against" (pp. 1787, 1789). During a summer heat wave we observed an excessive temperature elevation and subsequent massive muscle destruction (rhabdomyolysis) in a patient treated with a standard regimen of psychotropic agents. The surprise generated among colleagues spanning several institutions, specialties, and levels of tenure suggested a reexamination of life-threatening hyperpyrexia in patients treated with phenothiazines, neuroleptics of other classes, and other drugs commonly used concurrently to see to what extent these summer dangers have remained "little discussed" since Zelman and Guillan's report.

When one scans the major textbooks of psychiatry, internal medicine, and physiology as well as the much-consulted *Physicians' Desk Reference* (2) and *AMA Drug Evaluations* (3) one finds only the casual statement that "hyperpyrexia may occur" with neuroleptic treatment. No attention is directed to the degree of danger involved or to the compounding effects of agents used in conjunction with neuroleptics. Among textbooks of pharmacology Goodman and Gilman's volume (4) does mention the possibility of fatal hyperpyrexia associated with neuroleptic treatment and thus apparently contains the most direct source of this information in a readily available text. Even among manuals devoted to psychotropic drug side effects, Shader and DiMascio's book (5) appears to be alone in clearly mentioning temperature elevation as potentially dangerous.[1]

The *Cumulated Index Medicus* from 1970 to the present was scanned manually under the headings of Tranquilizing Agents, Tranquilizing Agents—Major, Phenothiazines, Psychopharmacology, Body Temperature, Body Temperature Regulation, and Fever. The computerized MEDLINE retrieval system was employed for a literature search back to 1969 using the subject headings of Tranquilizers, Major Tranquilizers, Hyperthermia, Fevers of Unknown Origin, Body Temperature, Body Temperature Regulation, and Body Temperature Changes. Finally, we examined the bibliographies of authors of those articles considered relevant in editions of *The Science Citation Index* dating back to 1970. This search revealed only a few pertinent articles and letters to the editor scattered throughout general medical, anesthesiological, and pediatric publications (6–10). Most strikingly, we found only one article devoted principally to this topic in a psychiatric journal (11). There is clearly a dearth of information on the seriousness of psychotropic drug-induced hyperpyrexia and, accordingly, a restatement of the problem is indicated.

PHYSIOLOGICAL IMPLICATIONS

The hypothalamus, the body's major center for thermoregulation, prevents overheating by both increasing perspiration and bringing heat to the body surface through peripheral vasodilation. Three avenues are available for the dissipation of bodily heat—radiation, conduction to objects and air, and evaporation of sweat. As the ambient temperature approaches that of the body, radiation and conduction will yield a net heat gain, rather than heat loss, leaving evaporation as the only major mechanism of heat loss. However, in dry air the healthy body is capable of maintaining a rela-

Dr. Mann is Staff Psychiatrist and Dr. Boger is Chief of Medicine, Veterans Administration Hospital, Bldg. 2, Coatesville, Pa. 19380. The authors are also with Jefferson Medical College, Philadelphia, Pa., where Dr. Mann is Clinical Instructor and Dr. Boger is Associate Professor, Department of Psychiatry and Human Behavior; Dr. Boger is also Clinical Associate Professor of Medicine.

[1]A detailed list of the various types of books discussed here is available from Dr. Mann on request.

tively normal body temperature in environments up to 130°F (54.5°C) (12). Heat is brought to the surface by dilated peripheral vessels and effectively lost through evaporation. High humidity will impair this mechanism, since less sweat can be lost to the already highly saturated air.

It has been known for some time that phenothiazines suppress thermoregulation at the hypothalamic level, leaving phenothiazine-treated animals vulnerable to high or low environmental temperatures (13). Similar hypothalamic suppression has been demonstrated in humans and forms the basis of the familiar therapeutic technique of phenothiazine-induced hypothermia. This hypothalamic suppression is a major mechanism by which life-threatening hyperpyrexia is caused. It occurs in varying degrees with neuroleptic agents of classes other than the phenothiazines and is apparently moderated through the effects of these agents on several centrally acting biogenic amines (14, 15).

Peripheral mechanisms are also important in producing hyperpyrexia. Neuroleptics exert peripheral *alpha*-adrenergic and cholinergic blockade of varying degrees. These effects run roughly parallel and are greatest with the so-called "low potency" neuroleptics such as aliphatic phenothiazines, piperidine phenothiazines, and chlorprothixene. With "high potency" agents such as piperazine phenothiazines, thiothixene, and haloperidol, these peripheral blockade effects are less marked. The adverse effects of such influences on thermoregulation at high temperature and humidity follow logically from the physiology discussed above. *Alpha*-adrenergic blockade widely dilates the peripheral vessels, depriving the body of insulation from the seething environment. Sweating, already impaired by high humidity, is further compromised by the well-known suppressing influence of cholinergic blockade, and heat loss becomes a potential impossibility. Antiparkinsonian agents, possessing great anticholinergic activity of their own, are the most common culprits in compounding the problem. Concurrent administration of tricyclic antidepressants, monoamine oxidase inhibitors, and lithium may further aggravate the situation in that they themselves may cause severe hyperthermia, acting presumably by a central mechanism (16). In addition, tricyclic antidepressants have marked anticholinergic activity.

Neuroleptics are also capable of causing hyperpyrexia in the absence of high environmental temperatures and by mechanisms less well understood than those described above. The neuroleptic "malignant" syndrome characterized by hyperpyrexia, muscular rigidity, and coma, first described by Delay and Deniker (17) and observed by others (18–20), has been discussed by Meltzer (20) as being possibly related to the syndrome of malignant hyperpyrexia.

Malignant hyperpyrexia is an autosomally inherited disease that predisposes individuals to react to potent inhalational anesthetics with a rapid and often fatal rise in temperature, frequently accompanied by muscular hypertonicity (21, 22). Elevated creatine phosphokinase (CPK) levels are found in a considerable number of patients who have recovered from this syndrome and also in asymptomatic relatives of patients so affected (22). CPK is an enzyme found in brain and in both cardiac and skeletal muscle. Numerous clinical conditions involving damage to these tissues, e.g., strokes, convulsions, myocardial infarctions, bodily trauma, multiple intramuscular injections, and muscular dystrophies, can cause elevated serum CPK values. The source of these elevations can be determined by specific isoenzyme assays. It is believed that the "resting state" elevations in CPK found in individuals with malignant hyperpyrexia reflect a subclinical myopathy that makes these patients vulnerable when stressed by the offending agent (22).

There have been repeated confirmations of the finding of elevated skeletal muscle CPK in both patients suffering from a wide variety of psychotic conditions and in their nonpsychotic relatives (23–26). Citing these findings and noting the similarity of neuroleptics to anesthetic agents implicated in malignant hyperpyrexia, Meltzer (20) has hypothesized a similar mechanism of disordered muscular function rendering certain psychotic patients—those with the highest CPK elevations—more likely to develop the neuroleptic "malignant" syndrome.

CASE REPORT

A 48-year-old male psychiatric patient had been hospitalized at Coatesville Veterans Administration Hospital for almost 3 years, and for 4 weeks he had been receiving 700 mg of chlorpromazine per day, 1.5 cc of fluphenazine enanthate I.M. every two weeks, and 6 mg of biperiden per day. Early on the morning of September 1 he eloped from the hospital and hitchhiked to central Philadelphia, which was in the midst of a record-breaking heat wave. Unable to gain entrance to a friend's apartment, he wandered the streets during the late morning and afternoon until he became dizzy and collapsed. It was not until evening that he was found lying unconscious on the sidewalk and brought by the police to a local hospital. There, still unconscious, he was described as exhibiting "purposeless chorioathetotic movements of the arms, but no seizure activity." His blood pressure was recorded as 70/0. He was dry and hyperpneic, and his eyes were fixed midline with pupils midpoint and reactive to light. There is no record of a temperature having been taken at the time. He rapidly regained consciousness and became "combative." Since his papers readily identified him as a psychiatric patient, he was transported to the Philadelphia Veterans Administration Hospital for treatment of what was considered to be an acute functional psychiatric disturbance.

The patient arrived at the Veterans Administration Hospital about 2 hours after being found by the police. He was alert and complained of leg cramps, weakness, and thirst. He was sweating and had a rectal temperature of 103°F (39.5°C). Blood pressure was 80/40 and heart rate was 140 beats per minute. No bruises or swelling were noted. Skin turgor was fair, and there was no apparent focus of infection. On neurological examination no focal abnormalities were noted, and

the "purposeless movements" were no longer present. However, moderate bilateral weakness of the upper and lower extremities was noted.

Sodium concentration was 140 mEq/liter; chloride, 102 mEq/liter; potassium, 6.4 mEq/liter; carbon dioxide, 13 mEq/liter; and blood urea nitrogen, 22 mg/ml. Hemoglobin content was 14.6 mg/100 ml, and white blood count was 15,700/cu mm. Arterial blood pH was 7.29; Po_2 was 70 mm Hg; Pco_2 was 25 mm Hg; and total bicarbonate was 11.6 mEq/liter. Chest X ray revealed no acute infiltrates. The clinical impression at the time was "hyperpyrexia and dehydration secondary to heat stroke." Blood, urine, and cerebrospinal fluid cultures were later reported as showing no abnormalities.

Initially, the patient responded well to fluid replacement, and urinary output was good. However, 5 hours after admission, urinary output fell to 40 cc per hour and responded little to mannitol infusion or furosemide I.M. Generalized muscle weakness progressed to almost complete flaccidity. Urinary myoglobin as determined by immunoassay was positive, and CPK rose rapidly to a peak of 166,700 units (normal is less than 45). This excessive elevation in CPK was indicative of massive muscle necrosis; a diagnosis of acute rhabdomyolysis was made and was subsequently confirmed by muscle biopsy.[2] Thus hyperpyrexia, with dehydration and hypotension, had caused massive muscle destruction leading to myoglobinuria and acute tubular necrosis.

A stormy course ensued and peritoneal dialysis was employed several times in the management of the impaired renal function. Over the course of several months the patient showed remarkable improvement in muscle strength. His renal function normalized surprisingly well. However, the severe renal damage that he had suffered contributed to an anemia that proved to be quite refractory to treatment.

DISCUSSION

Summer heat kills more than 4,000 people per year in the United States, with most deaths occurring in the humid urban areas (27). The typical individuals involved in heat morbidity are predisposed by chronic diseases such as arteriosclerosis, alcoholism, and diabetes mellitus. Such patients in particular and even persons not so predisposed are at greater risk when exposed to excessive thermal challenges if they are under treatment with psychotropic agents. As the body temperature rises above 106°F (41.1°C), damage to vital organs, e.g., brain, heart, liver, kidneys, and muscle, may occur (27, 28). The renal excretion of pigmentary breakdown products resulting from extensive muscle damage may lead to acute tubular necrosis. Hyperpyrexia can produce numerous abnormalities related to bleeding and clotting, including consumptive coagulopathy.

While three separate syndromes are usually delineated in association with high environmental temperatures, i.e., heat cramps, heat exhaustion, and heat pyrexia (heat stroke), considerable overlap exists (21). The fatalities reported by Zelman and Guillan (1) presented the classic picture of heat stroke—hot and dry skin, rectal temperature above 106°F (41.1°C), severe central nervous system disturbance, and an absence of sweating, indicating a potentially fatal breakdown in thermoregulation. Failure to employ aggressive measures promptly may result in death.

The patient reported here suffered severe hyperpyrexic morbidity resulting from an elevated body temperature probably well above the 103°F (39.5°C) recorded several hours after the termination of an extended exposure to excessive heat. That his body temperature had returned to 103°F (39.5°C) and that he was sweating when first seen at the Philadelphia Veterans Administration Hospital indicates a thermoregulatory apparatus sufficiently intact to enable his body to avail itself of the air-conditioned, dehumidified hospital receiving ward. This patient's symptomatology is best interpreted as a severe form of heat exhaustion—a syndrome characterized by hypotension and dehydration, but with unimpaired thermoregulatory capability. Even in the milder forms of heat exhaustion, the associated hypotension might prove particularly deleterious to patients with already compromised circulation, and the associated dehydration could precipitate lithium intoxication in those patients under treatment with lithium.

Psychiatric patients may be disproportionately exposed to summer heat and humidity, since many of them live in small, poorly ventilated city rooms and frequently wander aimlessly about the city streets. When sustained increased psychomotor activity is present in such patients, it results in a marked increase in body heat, making them particularly vulnerable to heat-induced illness. Hospitalized patients are also at risk, since many psychiatric inpatient facilities are not yet air-conditioned. Seclusion rooms are a specific concern because they are often small, hot, and lacking in cross-ventilation, and it is in such rooms that those patients who are most agitated, heavily medicated, and even struggling vigorously against restraints are often confined.

A primary consideration in minimizing the risk of hyperpyrexia should be the administration of neuroleptics in the lowest dosage effective in a given situation. While large doses of antipsychotic medication are frequently needed in treating acute psychosis, it has become quite evident that maintenance schedules are often unduly high. When large doses are required in extremely hot weather, drugs low in anticholinergic and anti-*alpha*-adrenergic activity, i.e., high-potency agents, should be preferentially selected. Rapid tranquilization and megadose techniques might best be employed with care during such periods. Most importantly, antiparkinsonian agents should not be prescribed prophylactically and should be withdrawn as soon as possible. Tricyclic antidepressants and lithium should be added to the therapeutic regimen with appropriate caution.

Awareness on the part of emergency ward physi-

[2]CPK elevations in the neuroleptic "malignant" syndrome have not been reported to approach the level seen in this patient.

cians, and psychiatrists in particular, of the potential of psychotropic drugs to cause life-threatening hyperpyrexia should ensure the more frequent recognition of this syndrome and the prompt initiation of appropriate therapy. The better recognition of drug-induced hyperpyrexia should reduce the indiscriminate prescribing of antibiotics and other medications in the management of psychiatric patients with fevers of unknown origin.

The type of treatment is dictated by the severity of the hyperpyrexia. In the case of heat exhaustion, removal to a cool environment, rehydration, and rest will generally suffice (21, 27). However, heat pyrexia (heat stroke) is a medical emergency. The patient must be immersed in an ice water bath to reduce rectal temperature to 101°F (38.3°C). Vigorous massage to promote dermal circulation is indicated. General measures to sustain the respiratory and cardiovascular systems are mandatory. For further details on the treatment of this life-threatening situation the reader is referred to *Harrison's Principles of Internal Medicine* (21) and Clowes and associates' report on heat stroke (27).

Psychosocial Aspects of a Tay-Sachs Screening Clinic

BY GERALD SCHNEIDERMAN, M.D., J. ALEXANDER LOWDEN, M.D., PH.D., AND QUENTIN RAE-GRANT, M.D.

The authors administered questionnaires to participants in a Tay-Sachs screening clinic. They received 322 responses. Although the majority of the respondents expressed anxiety about the possibility that they might be carriers, most indicated that this anxiety brought them to the clinic. The authors conclude that a well-publicized and well-organized screening clinic can function successfully and deal with the issue of anticipated loss without producing mass fear. An important factor in their clinic was the fact that they were able to offer an alternative to a Tay-Sachs child through amniocentesis.

CARRIER DETECTION PROGRAMS for genetic disease have come under attention recently because of scientific advances. We are studying the psychological effects of carrier screening programs on an involved population. The purpose of this paper is to examine a population participating in a Tay-Sachs screening clinic.

BIOCHEMISTRY AND GENETICS

Tay-Sachs disease is an inborn error of ganglioside catabolism (1–3) that affects young infants. The patient appears well at birth and develops normally for six to eight months, but then psychomotor degeneration begins. The child becomes blind and spastic, convulses frequently, and dies from aspiration pneumonia by the time he or she is three to five years old. The disease is caused by a defect in the activity of the enzyme hexosaminidase A, which normally hydrolyzes the β-1,3-glycosidic linkage between the terminal *N*-acetylgalactosamine and galactose in the G_{M2}ganglioside molecule. The lipid cannot be catabolized and is stored in large amounts in nervous tissue and in smaller amounts in other organs. The disease is 100 times more common in Jewish infants than in others. Among Ashkenazi Jews, the calculated carrier frequency is 1 in 30 (4) to 1 in 15 (5).

The total hexosaminidase activity varies greatly from one individual to another, but the percentage accounted for by hexosaminidase A is relatively constant. By measuring the percentage of hexosaminidase A in serum or tissues, affected infants can be identified and carriers of the genetic disorder detected with a high degree of accuracy. The enzyme is normally present in the amniotic fluid cells and cultured fibroblasts, so that the diagnosis can be made in utero by amniocentesis (6).

Because heterozygote detection is relatively simple, because the disease is far more common in a defined population group, and because a simple and accurate test is available for antenatal diagnosis, mass carrier screening programs have been undertaken to search for heterozygotes in families with no previous history of Tay-Sachs disease.

PREVIOUS STUDY

In a previous study we interviewed 95 families two years after they had participated in a testing program (7). We observed families who were presented with the possibility of losing a child. Their anxiety was heightened while they were undergoing testing and waiting for the results. However, this was followed by relief for the unaffected families and a cautious optimism for carrier couples. In all of the families interviewed there was no long-term morbidity.

Although the screening program stirs up feelings in the families about life and death, amniocentesis allows families to face the anxiety produced by the testing program with the knowledge and the resulting hope that affected families can still produce normal, healthy children.

PRESENT STUDY

Our latest study is prospective and involves the clients who came to a Tay-Sachs clinic on the day of screening. Questionnaires were given to all of those who came for testing.

Presented at the Annual Research Day, Department of Psychiatry, University of Toronto, Toronto, Ont., Canada, September 10, 1976.

Family Backgrounds

The number of questionnaires answered was 322. The average age of the married men who answered the questionnaire was 30.97, and the average age of the married women was 28.77. The average number of children per family was 1.91. The average age of the single men who answered the questionnaire was 22.54; that of the single women was 22.05. The occupational levels according to Hollingshead and Redlich varied from class I to class IV, but 82.6% were in classes I and II.

Observations and Findings

The medical staff of the local community hospitals had organized publicity for the screening clinic through television, radio, and newspapers and through local synagogues. They spoke to local lay groups about the clinic and educated volunteers to work in the screening clinic. On the days that the clinic was held, medical personnel were in attendance to answer questions.

The clinic was efficiently organized and staffed by volunteers who helped participants feel less anxious. Their knowledge enabled them to answer queries with comfort and ease. In general, women asked questions more directly; the men phrased their questions in a jocular defensive manner. Enough technicians were available that the wait to have blood taken was short. Coffee and light snacks were available for the participants.

Several single women who were about to be married questioned the medical personnel about Tay-Sachs; they were very concerned about their future should they and their fiancées both be carriers. The physician's response was to separate the issues of marriage and Tay-Sachs disease.

According to the questionnaires, in 75% of the married couples testing was initiated by the wife. Although some of the respondents were misinformed on a number of facts about Tay-Sachs disease, most of them understood the concept of the disease. Seventy percent favored abortion of an affected fetus, but 29% of the group who answered the questionnaire did not respond to this question. Although 75% of the respondents expressed anxiety about finding that they were carriers, the majority indicated that anxiety is what led them to participate in the clinic. Although some of the respondents had misgivings about participating—such as the fear of blood and needles—these were temporary. The majority of the participants felt that the program was worthwhile and helpful and were pleased that it was available. When asked about their feelings about the future of the Jewish family as an institution in the light of the fact that Tay-Sachs disease occurs predominantly in Jewish families, 25% of the respondents expressed concern.

DISCUSSION

Our findings indicate that a well-publicized and well-organized clinic can function successfully and deal with the issue of anticipated loss without producing mass fear and hysteria. The important issue is that the clinic offers an alternative to a Tay-Sachs child through amniocentesis. Our previous findings showed that there were no long-term psychological sequelae to a screening program. Although the participants expressed anxiety, they were reassured by the volunteer and medical staff.

The one major area of concern occurred in single people about to be married. It should be pointed out that marriage and preventable genetic disease are separate issues and ought not to be connected in making a choice of partners. We hope that the Tay-Sachs screening program will serve as a model for the prevention of other genetic diseases (8).

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Recidivism Among Sex Assault Victims

BY JILL MILLER, DEBORAH MOELLER, R.N., ARTHUR KAUFMAN, M.D., PETER DIVASTO, PH.D., DOROTHY PATHAK, PH.D., AND JOAN CHRISTY

The concept of recidivism has traditionally been applied to the assailant in a crime. However, recent work in the field of victimology has evolved a concept of victim recidivism. A recent national survey of victims of violent crimes revealed that 28% were prior victims of violent crime (1). Data on rape victims, however, were not included in the survey.

A growing body of medical literature on sex assault victims concerns itself primarily with the impact of the assault on (2, 3) and the proper treatment of (4, 5) the rape victim. However, data on the prevalence and characteristics of rape victim recidivism also deserve examination for they might shed light on risk factors for potential victims in the population. We obtained information relevant to this subject from the data sheets completed for rape victims seen by the Sexual Assault Response Team of the Department of Family, Community, and Emergency Medicine of the University of New Mexico School of Medicine over a 2½-year period.

Method

The University of New Mexico School of Medicine Sexual Assault Response Team has been providing immediate crisis intervention, medical assistance, and long-term follow-up counseling for sexually assaulted victims and their families since 1974. The team consists of medical and nursing students who rotate on a 24-hour call schedule to the emergency room of the county teaching hospital of the medical school. Each team member completes a victim data form, which includes information concerning demographic data, nature and circumstances of the assault, previous assaults, previous need for counseling, emotional and physical condition of the patient, and resulting medical treatment and legal disposition. We reviewed the data forms on 341 victims seen from January 1975 to June 1977 for information relative to past sexual assaults. Data on rape victim recidivists were matched against those of first-time victims, and both groups were then compared to general population statistics for the Albuquerque metropolitan area.

Results

Of the 341 victims seen, 82 (24%) were recidivist victims of sexual assault. The average ages of first-time and recidivist victims were 24 and 23 years, respectively, an insignificant difference. The distribution of educational attainment between both the first-time and recidivist groups was also similar.

In the first-time group, 11 of the 259 contacts (4%), were incestuous whereas of the 82 recidivist victims 15 (18%) of the prior assaults involved incest. This difference is highly significant ($p<.001$).

Tabulation of the economic status of victims 18 years or older (72% of each group) revealed that 33 of 186 first-time victims (18%) compared with 19 of 59 recidivist victims (33%) were either unemployed or receiving public assistance. This difference was also statistically significant ($p<.05$). A measure of relative transiency among all victims showed that 80 of the 259 first-time victims (31%) were recent arrivals (lived in Albuquerque less than one year), whereas 41 of 82 recidivists (50%) were recent arrivals. This difference in proportions is again highly significant ($p<.005$).

A comparison of the two groups' past emotional problems revealed that 54 of the 259 first-time assault

Ms. Miller is a medical student and Ms. Moeller is a nursing student, University of New Mexico. Dr. Kaufman is Associate Professor, Drs. 0002-953X/78/0009-1103$0.35 © 1978 American Psychiatric Association

victims (21%) had previously sought professional help for emotional problems, as had 39 of the 82 recidivists (48%). This difference, too, is highly significant ($p<.001$).

An ethnic comparison of each group with the general Albuquerque population revealed significant differences (see table 1). A major part of the extremely high χ^2 value of the difference of the first-time victims from the general population (observed $\chi^2_3=174.4$, $p<.0005$) was due to the much larger proportion of American Indians in the first-time assault group than in the general population. The observed proportions of American Indians and blacks were larger than expected, while the Chicano proportion was smaller than expected. For the Anglo, the proportion was about the same as expected, i.e., smaller in the first-time victim group than in the general city population and about the same in the recidivist group.

TABLE 1
Ethnic Comparison of Albuquerque Population Census (1970) with First-Time and Recidivist Sex Assault Victims

	City Population (N=243,751)		First-Time Victims (N=259)		Recidivists (N=82)	
Ethnic Group	N	%	N	%	N	%
Anglo	148,122	61	129	50	53	65
Chicano	85,032	35	89	34	17	21
American Indian	3,351	1	34	13	5	6
Black	5,425	2	7	3	7	8
Other	1,821	1				

Discussion

It is likely that the proportion of sex assault recidivism is even higher than the 24% evident in our survey. Many of these data were collected in a crisis setting not necessarily conducive to sensitive historical revelations. In follow-up counseling sessions, many victims revealed for the first time prior incidents of sexual assault. However, some victims did not avail themselves of follow-up services.

For the majority of recidivist victims, treatment for the current assault provided them their first opportunity to discuss the prior assault(s). It was a recurrent observation of many Sexual Assault Response Team members that the trauma of the current assault could not be resolved until the prior assault(s) was adequately addressed. Team members also observed an almost fatalistic attitude toward the current assault among members of this group. There were numerous incidents of violence and abuse in their lives and the current assault seemed just one more in a long series of traumas.

The higher proportion of unemployment among recidivists may reflect the societal association of poverty and crime. In some cases, such as hitchhiking because one does not own a car, this relationship is straightforward. In others, it is less apparent. The unemployment figure may also be indicative of a group less able, for social, physical, or psychological reasons, to obtain and keep a job. These persons may be less effective in overall living and thereby may be easier prey for perpetrators of sexual assault. As a final hypothesis, the unemployment may reflect a lifestyle choice that does not require formal employment.

Another notable feature of this group of patients is their transiency. A large number of them appeared rootless. Some were runaways and had been for months or years. This population is especially at risk for exploitation since they must rely on strangers for food and shelter, which increases their chances of sexual assault. Still others were recent arrivals in the city and, perhaps, not yet "street wise."

The greater prevalence of prior emotional disturbances among recidivist victims may suggest behavioral characteristics that increase their vulnerability to sexual assault. A number of victims in this group were either known or suspected of being either mentally retarded or severely disturbed. Their ability to judge external danger appeared to be grossly impaired. Some exhibited a naive trust of their environment that probably contributed to their assault.

Based on observations of the Sexual Assault Response Team members, recidivist victims were more likely to come from disruptive homes and live a more chaotic lifestyle than first-time victims. Many appeared to have such strong dependency needs that they were recurrently taken advantage of financially and sexually.

An area inviting exploration is whether recidivist victims are more likely to exhibit repetitive destructive behavior patterns. The overwhelming majority of recidivists in our survey had failed to receive medical or counseling services after their prior assaults. If such services had been received, such intervention might have provided insight, support, and modification of their behavior, rendering them less vulnerable to future assaults.

Sodium Nitroprusside Treatment of ECT-Induced Blood Pressure Elevations

BY DOMINIC CIRAULO, M.D., LEONARD LIND, M.D., CARL SALZMAN, M.D., ROBERT PILON, M.D., AND ROBERT ELKINS, M.D.

Electroconvulsive therapy (ECT) transiently raises blood pressure (1). This hypertensive response is independent of convulsive activity and is thought to result from a rise in peripheral catecholamines secondary to central sympathetic stimulation (1, 2). Patients who are hypertensive often show greater ECT-related increases in blood pressure than those who are normotensive (3). Atropine, which is routinely used as a pre-ECT medication to suppress vagal stimulation, elevates blood pressure further (3), as does succinylcholine, which is used for muscle relaxation (4). In this paper, we will describe a case in which the blood pressure of an elderly hypertensive patient was controlled by using intravenous sodium nitroprusside during each treatment. This technique proved to be simple, reliable, and successful in controlling the potentially hazardous elevations of blood pressure.

Case Report

A 70-year-old man was referred for ECT because of a severe recurrent depression that was resistant to antidepressant medication. The patient had long-standing hypertension as well as ECG evidence of an old myocardial infarction. Two years earlier he had been given ECT for a similar depression. Despite concomitant antihypertensive therapy at that time, blood pressure elevations as high as 240/160 were recorded during the ECT procedure.

During the first treatment in the present ECT series, his blood pressure rose to 250/140. Sodium nitroprusside infusion was used in the remaining 9 ECT treatments, and blood pressure was transiently elevated only to 190/120. He responded well to an otherwise uneventful course of ECT.

Sodium nitroprusside was prepared by mixing 50 mg with 500 cc of 5% dextrose in water just before use; the mixture was shielded from light. The rate of intravenous infusion was titrated according to the patient's blood pressure using a microdrip infusion set. The infusion was begun 15 minutes before ECT and was continued for 5 to 15 minutes following the treatment. In this patient, there were no adverse effects from the nitroprusside infusion, other than transient hypotension during 1 treatment, which was easily controlled by discontinuation of the nitroprusside.

Discussion

The use of nitroprusside in the treatment of hypertension and the control of blood pressure has been well described in the literature. In the late 1920s, Johnson (5) first discussed the potential utilization of nitroprusside in the therapy of hypertensive crisis. The first clinical report of the use of nitroprusside in hypertensive emergencies was made by Page in 1951 (6). In current medical practice, nitroprusside is commonly used for rapid control of hypertensive crises, production of hypotension during surgery to minimize blood loss and obtain "dry" operative fields, and induction of afterload reduction in the treatment of myocardial infarction, dissecting aortic aneurysm, and marked congestive heart failure (7).

Intravenous infusion of sodium nitroprusside results in rapid lowering of arterial blood pressure, with a concomitant decrease in total peripheral resistance. There is a rapid return of the blood pressure to control values after the infusion is discontinued. Heart rate will increase in most patients as a secondary response to a rapid decrease in arterial blood pressure. Dilation of peripheral capacitance and resistance vessels increases pooling of blood and decreases myocardial preload and afterload (7, 8).

The site of action of sodium nitroprusside is at the vascular smooth muscle membrane; therefore, nitroprusside is considered a direct-acting vasodilating agent. The nitroprusside molecule is believed to interact with sulfhydryl groups of the vascular smooth muscle membrane to produce muscle relaxation (9). In general, toxicity is encountered with prolonged administration and rapid infusion rate and results from release of cyanide from the nitroprusside molecule (7). A maximum dose of 3–5 mg/kg of nitroprusside is recommended, with a suggested rate of infusion between 0.5 and 1.5 μg/kg per minute (10). The dangers of sodium nitroprusside use during anesthesia include those associated with hypotension and cyanide poisoning (7, 10).

In summary, sodium nitroprusside appears to be useful in controlling potentially dangerous elevations in blood pressure in hypertensive patients receiving ECT.

Hysteria and ABO Blood Types

BY PANTELIS M. RINIERIS, M.D., COSTAS N. STEFANIS, M.D., ELEFTHERIOS P. LYKOURAS, M.D., AND ELEFTHERIA K. VARSOU, M.D.

Associations between ABO blood types as genetic markers and certain mental diseases, such as schizophrenia, unipolar and bipolar depression, and obsessive-compulsive neurosis have been reported (1–3). Since, to our knowledge, no attempt has been made to investigate a possible association between ABO blood types and hysteria, the development of which seems to involve genetic factors (4), we carried out a study to explore this possibility.

Method

We studied 75 subjects (21 men and 54 women) who had been diagnosed by 2 independent psychiatrists (P.R. and E.L.) as suffering from hysteria according to the criteria of Feighner and associates (5), i.e., the patients were suffering from a chronic or recurrent illness that began before age 30, and were manifesting at least 25 medically unexplained symptoms in at least 9 of the following groups:

1. Headaches, sickly during majority of life.
2. Blindness, paralysis, anesthesia, aphonia, fits or convulsions, unconsciousness, amnesia, deafness, hallucinations, urinary retention, difficulty in walking, other unexplained "neurological" symptoms.
3. Fatigue, lump in throat, fainting spells, visual blurring, weakness, dysuria.
4. Difficulty in breathing, palpitation, anxiety attacks, chest pains, dizziness.
5. Anorexia, weight loss, marked fluctuations in weight, nausea, abdominal bloating, food intolerances, diarrhea, constipation.
6. Abdominal pain, vomiting.
7. Dysmenorrhea, menstrual irregularity, amenorrhea, excessive bleeding.
8. Sexual indifference, frigidity, dyspareunia, other sexual difficulties, vomiting all 9 months of at least one pregnancy or hospitalization for hypermesis gravidarum.
9. Back pain, joint pain, extremity pain, burning pains of the sexual organs, mouth, or rectum, other bodily pains.
10. Nervousness, fears, depressed feelings, need to quit working or inability to carry on regular duties because of feeling sick, crying easily, feeling life was hopeless, thinking a good deal about dying, wanting to die, thinking about suicide, suicide attempts.

Fifty of these subjects were hospitalized and 25 were seen and followed at the outpatient clinic of the Eginition Hospital in Athens.

ABO blood types were determined on a blind basis by a single technician who had extensive blood typing laboratory experience. The typing was carried out by the standard method adopted by most transfusion centers (6).

To compare our findings with a control sample we used the data provided by Valaoras (7) on ABO blood type distribution in the Greek population.

Results

Table 1 shows the distribution of ABO blood types in the male, female, outpatients, and inpatient subgroups, in the total sample, and in the control sample.

No significant difference was found between the male and female patients and between outpatients and inpatients in relation to their ABO blood types distribution pattern (chi square analysis). The combined patient subgroups had a significantly higher incidence of blood type A ($\chi^2=17.69$, df=1, $p<.001$) and a significantly lower incidence of blood type O ($\chi^2=8.81$, df=1, $p<.01$) than normal controls.

Discussion

A significantly higher incidence of blood type A was found in our patients with hysteria than in controls. This finding suggests an association between hysteria and phenotype A. Since the significance of the relationship between blood groups and disease is still un-

Dr. Rinieris is Senior Lecturer, Dr. Stefanis is Professor and Chairman, and Drs. Lykouras and Varsou are Lecturers, Department of Psychiatry, Athens University Medical School, Eginition Hospital, 74 Vasilissis Sophias Ave., Athens 611, Greece. Address reprint requests to Dr. Rinieris.

Amitriptyline-Induced Obesity in Anorexia Nervosa: A Case Report

BY KENNETH S. KENDLER, M.D.

In a significant proportion of patients anorexia nervosa is preceded or followed by obesity (1). In such patients, it is likely that an abnormal CNS body weight "set-point" underlies their illness. Amitriptyline treatment, which can produce modest weight gain in anorexia nervosa (2, 3), produced obesity in the following case. This patient's body weight set-point may have been altered by amitriptyline, which raises questions about the neurochemical basis of this set-point and the relationship of anorexia nervosa to affective illness.

Case Report

Ms. A was a 20-year-old, 155-cm-tall woman with an ideal body weight of 47 kg. She had never been obese as a child, and reached her maximum weight of 46.5 kg at age 14. At 17, weighing 43.5 kg, she became amenorrheic. Significant weight loss began in February 1977. In July, weighing 28 kg, she was hospitalized on a psychiatric service. On admission, she was emaciated and had a distorted body image, compulsive hyperactivity, and a marked fear of obesity. She denied hunger and experienced early satiety upon eating. Her affect was sullen and depressed, with prominent feelings of helplessness and worthlessness. However, other psychiatric symptoms or signs were absent. A thorough medical and neurologic work-up was negative.

The patient was placed on a behavior modification regimen and gained 10.5 kg over an 8-week period. She was then placed on an ad lib diet and lost 2.5 kg over 2 months. In November, weighing 36.0 kg, she was started on amitriptyline, 100 mg/day. Within 8 days her appetite increased and she gained 1.0 kg. She was then discharged to outpatient therapy. Over the next 7 weeks she gained over 1 kg a week, weighing 49 kg by January. She stated that she felt hungry all the time and despite the consumption of large amounts of high-calorie foods rarely felt satiated. Her mood and outlook brightened and she was less sullen. Her weight gain slowed so that the next month she weighed 52.5 kg. At this time she stopped taking amitriptyline. Her weight gain continued despite the return of a depressed mood, helplessness, hopelessness, and, this time, suicidal ideation. By March her weight was 59.5 kg and had appeared to stabilize.

In summary, while on amitriptyline, Ms. A went from a stable, partially treated state of anorexia nervosa to moderate obesity. Despite the discontinuation of the drug, she continued to gain weight, reaching a weight more than 25% over her ideal weight. While she was on amitriptyline, her eating pattern changed from one of lack of hunger with early satiety to persistent hunger and lack of satiety.

Dr. Kendler is a resident, Department of Psychiatry, Yale University School of Medicine, 34 Park St., New Haven, Conn. 06519.

0002-953X/78/0009-1107$0.35 © 1978 American Psychiatric Association

Discussion

Amitriptyline is thought to act predominantly by blocking the reuptake of serotonin (4). The neurochemical control of appetite and body weight, which is poorly understood, probably involves several neurotransmitters. On the basis of animal work, however, it has been proposed (5) that serotonin is involved in determining body weight set-point such that increased functional serotonin would lead to an increased body weight set-point and would then produce increased appetite and decreased satiety until that new increased body weight was reached.

Anorexia nervosa has been shown to be genetically related to affective illness (1). One form of affective illness, bipolar disease, can be viewed as an abnormality in a CNS set-point function, in this case of mood. The close relationship between the set-points of mood and body weight is demonstrated by observations going as far back as Kraepelin (6) that depression is associated with anorexia and weight loss and that hyperphagia, often accompanied by weight gain, occurs in hypomanic and manic states. In a recent case report (7), both mood and body weight set-points were "reset" by pharmacologic intervention; combined chlorimipramine (a specific serotonin uptake blocker) and tryptophan produced obesity and hypomania in a depressed anorectic woman.

Some individuals with anorexia nervosa may have an abnormality in body weight set-point that is related to the abnormality of mood set-point that occurs in bipolar affective illness. Just as in a depressed person without a bipolar diathesis amitriptyline can produce a gradual return to euthymia, so amitriptyline often produces mild weight gain (8). But, again, just as in a person with a bipolar diathesis amitriptyline can produce a marked swing of mood set-point resulting in hypomania or mania (9), in certain cases of anorexia nervosa it may produce a wide swing in body weight set-point resulting in obesity.

In summary, in this case amitriptyline therapy was associated with the production of obesity in a patient with anorexia nervosa. Because of the phobic fear of obesity in many anorectic patients, this is a potentially significant side effect of amitriptyline treatment for this condition. I postulate that amitriptyline produced this effect by its actions on the serotoninergic body weight set-point system. I further suggest that the underlying pathophysiology of those cases of anorexia nervosa that alternate with spontaneous or drug-induced obesity may be an abnormal body weight set-point. This abnormal body weight set-point may be closely related to the abnormal mood set-point of bipolar affective illness.

Intrapatient Responses to ECT and Tricyclic Antidepressants

BY WILLIAM CORYELL, M.D.

This paper reports the results of a chart review comparison of the therapeutic efficacy of ECT and tricyclics in patients who received ECT during one depressive episode and a tricyclic during another.

Method

The records of all inpatients with depressive illness who received ECT at the Iowa Psychiatric Hospital between 1920 and 1959 were screened for those patients who had records of subsequent discrete episodes treated on an inpatient or outpatient basis between Jan. 1, 1961, and Dec. 31, 1976. The resulting sample of ECT-treated depressive episodes was therefore not biased toward greater severity by the availability of antidepressant therapy. Because the Iowa Psychiatric Hospital has traditionally been a tertiary care center, a large number of patients received tricyclic therapy at the hospital after 1960 only when similar attempts elsewhere had failed. This obvious

Dr. Coryell is Assistant Professor in Psychiatry, The University of Iowa College of Medicine, 500 Newton Rd., Iowa City, Iowa. 52242.

0002-953X/78/0009-1108$0.35 © 1978 American Psychiatric Association

source of bias was avoided by eliminating all patients who had received more than 4 days of antidepressant therapy before referral. To ensure that the episode in question was distinct from that involving earlier ECT treatment, patients who had not had an intervening period of treatment-free remission were eliminated from the sample. Selection criteria also required that ECT and antidepressant treatment efforts meet the criteria for adequacy defined in an earlier chart review by Avery and Winokur (1). Finally, all patients met *Research Diagnostic Criteria* (*RDC*) criteria (2) for primary major depressive disorder.

The present study and that by Avery and Winokur (1) defined treatment response identically, except that the response rater in this study was blind to the patient's identity and therefore rated responses to each of the two treatment modalities without knowledge of the nature of response to the other. Notes by all physicians and ward personnel made over a 4-day period before discharge and a hospital course summary were used to assign patients to one of three categories: not improved, improved, and completely recovered. In cases of outpatient treatment efforts, outcome was assessed from the clinic note that fell closest to 6 weeks after the treatment was started. The rater used the "completely recovered" category only when no evidence of symptomatology could be found among those notes.

Results

Of the 3,264 individuals admitted with depressive disorders between January 1920 and December 1976, only 42 had admissions during both of the defined periods (before Dec. 31, 1959 and after Jan. 1, 1961). Only 11 inpatient and 4 outpatient tricyclic antidepressant treatment efforts satisfied the remaining selection criteria.

The mean ages at the time of ECT and antidepressant treatment efforts were 44.3 years and 55.1 years respectively (see table 1). The duration of depressive symptomatology before the onset of treatment was nonsignificantly longer for ECT treatment efforts. However, duration of hospitalization was significantly shorter than that for antidepressant treatment efforts.

An exceedingly high rate of recovery was noted among ECT treatment efforts. Only 1 out of 18 efforts (3 patients had 2 separate episodes treated with ECT) showed less than complete recovery. Recovery rates were also high for antidepressant treatment efforts; 8 of 15 patients were categorized as completely recovered. Five patients manifested some improvement while only two patients showed no improvement to antidepressant treatment. The difference in response ratings between treatment groups was significant ($\chi^2=7.70$, df=2, $p<.025$). Since no patient failed to respond to ECT, response to antidepressants in previously ECT-resistant patients could not be addressed. The one ECT treatment effort that was rated improved rather than recovered was followed by complete response to antidepressants in a later episode.

TABLE 1
Comparison of Intrapatient ECT and Tricylic Antidepressant Responses

Item	Treatment Episodes: ECT (N=18)*	Treatment Episodes: Antidepressant (N=15)
Mean age at time of treatment (years)	44.3	55.1
Mean duration at onset of treatment (weeks)	18.1**	13.1
Mean duration of hospitalization (days)	36	49***
Rating (in percent)		
Completely recovered	94	53
Improved	6	33
Not improved	0	13

*Includes 3 patients who received ECT for 2 separate episodes; thus, percents are based on number of treatment efforts rather than number of patients.
**$p<.02$, two-tailed t test.
***Applies only to 11 inpatients.

Discussion

These data provide evidence that the efficacy of ECT is superior to that of the tricyclics when these treatments are compared *within* individuals. Such findings are complementary with another chart review study (1) and with well-controlled evaluations of ECT versus tricyclics (3).

Although there is no literature indicating decreasing efficacy of tricyclic antidepressants with age in a given individual, there is a good deal of evidence that the length of depressive episodes increases with age. This factor may have influenced the results reported here. In this sample, however, duration of episodes at treatment onset did not differ significantly between ECT and tricyclic antidepressant treatment efforts.

Other factors included in this design had the potential to reduce artificially the apparent efficacy of tricyclic antidepressants. The group excluded because of inadequate duration of treatment effort might have included patients who responded quickly. As it happened, in this sample all patients excluded because of an inadequate trial of tricyclics required ECT before discharge.

The response patterns presented here are appropriately compared with those noted by Avery and Winokur using identical rating methods. In a large sample reduced by relatively few exclusion criteria, 49% of patients receiving ECT alone showed complete response, whereas only 26% of patients receiving adequate antidepressant therapy alone were so rated. The relatively high quality of response to both modalities we observed was unexpected and deserves comment. The selection criteria resulted in a sample featuring recurrent and definitely discrete episodes. Onset tended to be abrupt. Since patients who experienced good

treatment response in an earlier episode are more likely to go to the same treatment facility without first seeking help elsewhere, our selection probably biased the sample toward patients who respond well to ECT.

Data from a similar but larger study would be relevant to the issue of specificity of different treatment modalities. The present study illustrates the difficulty in obtaining a sample that is both large and unbiased.

LETTERS TO THE EDITOR

This section contains reactions to Journal *articles, statements of opinion, comments on Association activities, requests for information, etc. Letters should be submitted in duplicate to the Editor, who makes all decisions regarding publication. Letters must be typed double spaced throughout and should not contain more than 500 words and 5 pertinent references. Criticisms of published articles will automatically be sent to the author(s) for response. Letters will be edited for clarity and conformance with* Journal *style. We regret that we cannot inform writers of the disposition of letters or return those which are not printed.*

Other Views on Women in Psychiatric Residency

SIR: We are quite concerned that some of the serious discriminative abuses outlined by Elissa P. Benedek, M.D., and associates in "Problems for Women in Psychiatric Residency" (November 1977 issue) are occurring in any psychiatric residency program(s) in this country. Unfortunately, the authors did not report where, over what period, and with what frequency the incidents occurred. We would like to provide a contrast: the experience of women residents at the University of Pittsburgh. None of the 12 women currently in training could recall a seductive supervisor. No woman resident has been barred from a clinical service or from working with a particular type of patient because of her gender. Committee assignments, administrative responsibilities, and chief residency appointments are equally available to all residents who merit them. Both men and women residents plan and participate in study, athletic, and social group activities.

Qualified applicants for psychiatric residencies are in increasingly short supply. This is another reason why no resident should feel that he or she must tolerate a discriminatory training program. Women, like all minorities, are at risk for scapegoating in environments that permit such practices. Where each resident is respected as a colleague and dealt with fairly, all should benefit.

We consider the Benedek and associates article unduly polarizing. Men too can have unfortunate experiences with paternalistic or authoritarian supervisors who are unable to separate their personal attitudes from their supervisory efforts. In informal meetings in our program, as well as in residents' process groups, men express feelings of isolation, loneliness, depression, and/or conflicts between professional training and family needs as often as women do. Residents of both sexes have potential problems of prolonged dependency on (or fear of surpassing) a research, clinical, or administrative mentor. In some cases, although male residents share similar concerns (e.g., safety), they may permit the women to appear more anxious and fragile by speaking of these concerns for their female colleagues only.

There are, of course, some problems not shared by male residents. The resident who is pregnant or nursing a child must have a flexible work arrangement. Admittedly, it is not simple to reconcile the needs of the resident and her family with the needs of other residents and the patients. It certainly is true that there are insufficient female role models for women in academic psychiatry. Two solutions we find helpful are interactions with outstanding women from other programs (most often at national meetings) and the use of more senior women residents within our own program as role models. We also agree that many supervisors lack cognitive knowledge of female psychology, a subject that is often omitted from curriculum planning. We would recommend, instead of a separate course on the psychology of women, the integration of male and female psychology into the psychiatric curriculum for residents and for their supervisors.

In summary, we endorse Dr. Benedek and associates' attention to the problems of women residents. However, we must criticize their ambiguous data and their polarization of issues along exclusively gender lines. We hope that those concerned with psychiatric education will not be distracted by their few glaring examples and miss the more subtle, but extremely important, issues that are also described in their paper. We agree with the substance of their concluding recommendations, with the provision that these should apply to, and will benefit, *all* residents and their patients. Finally, a systematic collection of data on the current situations of women residents in psychiatry is clearly needed.

MINA D. KESSLER, M.D.
JUDITH HENSON, M.D.
Pittsburgh, Pa.

SIR: We would like to dissociate ourselves from the remarks of Dr. Benedek and associates in the November 1977 issue lest they be seen as speaking for all or most women in American psychiatry. There is no doubt that women in medicine do face some very special problems, most of which are related to the constant pull between career and family obligations—a struggle that men entering medicine also experience. That these problems are magnified by training in and practice of psychiatric medicine, however, seems to be more a product of the rather narcissistic view of the authors than the specialty itself. Placing the "supervision" experience at the core of psychiatric training, the authors perceive particular difficulty in dealing with attitudes of aggression and sexuality of supervisors, whether male or female. The authors see women residents as victims of homoerotic fancy, chauvinistic competition, or savage mothering by females and patting, handholding, dinner invitations, or "even more flagrantly seductive ways" of stereotyping chauvinists of male gender and deplore their exclusion not only from the "unique and real relationships" women crave with their peers but also from committee assignments, team leadership, and individuation. The latter process would indeed do well to have been completed considerably before undertaking psychiatric residency.

We cannot wait for supervision to achieve our identity as women. A woman's gender identity is formed long before—

from parents and grandparents, teachers, Girl Scouts and camp, schoolyard brawls, parties and proms, from elections and love affairs lost and won. Bewailing the absence of female role models as administrators in psychiatry, the authors do not seem to have entertained the notion that many women have eschewed administrative posts because they are too smart to get stuck with them. Administration is tiresome and unrewarding compared with patient care or the struggle for enlightenment in library and laboratory and is seen by many of us as an unutterable bore, suited for those whose appetite for power is equaled by their tolerance for ennui and frustration.

Finally and most seriously, the authors seem to have missed the point on the "projection of an image of competency." Contrary to their assertions, it has very little to do with handling a microphone with aplomb. It has everything to do with doing a job well, with dignity, ability, courtesy, and compassion. Respect and admiration from male colleagues will be earned by first-class work, not by harangue or even consciousness raising. As for research careers—allegedly closed to women because of absent role models, geographic inconvenience, or insufficiently "nurturant" males—their main ingredients are curiosity, keen observation, conjecture, imagination, discipline, and long hours, and few men or women can achieve such careers without tremendous sacrifice by themselves and their families. This brings us to what seemed the most glaring omission in the paper—families. It is extremely difficult for a man or woman to combine a full family life and a major career commitment without an extraordinary trinity behind him or her . . . the spouse, children, and, in the case of a woman, the housekeeper. At least for the present, the career woman with a family is still the mother and is therefore principally responsible for child care and homemaking. Most men with significant careers in medicine already know that spouses of doctors must be "superpeople"—superconfident, supergiving, and supertrusting. As women working for equal opportunity in a demanding profession, we must be pretty well past the stages of individuation and nurture-demanding. We enter a medical career not to individuate but because we *are* individuals and find joy and fulfillment in giving time, energy, and, one hopes, health to people who need our services. As for nurturing, medicine is not a restaurant; perhaps only the reasonably well-fed should apply.

Dr. Benedek and Associates Reply

SIR: We appreciate the various responses we have received to our article, some formal, some informal, expressing varying degrees of support of or disagreement with our viewpoint. We feel this indicates that our chief goal in writing the article has been reached, namely, raising an area of concern and facilitating a reaction in our readers.

First of all, we wish to clarify that the views and vignettes presented in the paper were not idiosyncratic to us. Editorial space constraints precluded elaboration of the fact that this paper was an outgrowth of a panel on the unique problems of female residents in psychiatry, originally presented at the American Psychiatric Association annual meeting in 1973. The five panelists, residents, or individuals who had recently completed training, presented their own personal experiences and also incorporated those of many other female colleagues from training programs in different parts of the country.

It is important to point out that our motivation in presenting the panel was not to generate research data about women residents but to raise some relevant issues in order to stimulate comparison and contrast by the audience. In fact, the subsequent discussion led us to present a similar panel the following year that paired the original panelists with male counterparts to stimulate even more audience participation. Although the material presented by the men was very relevant and important from the standpoint of residency training, and we acknowledge a certain commonality of stereotyping experiences by both sexes, we chose to focus on the female experience because we wished to emphasize that some of the problems faced by women residents are unique to them because of their gender.

One criticism leveled at us was that our paper seemed very negative as well as idiosyncratic. We certainly were not saying that the entire residency experience, or any segment of it, was basically negative. Indeed, had that been the case, none of the women involved would have stayed in their training programs or perhaps even in the field of psychiatry. Our goal was to highlight certain issues, not for purposes of condemnation but to facilitate awareness and constructive change where appropriate.

Some women have written with sharp claims that none of the phenomena described by us apply to their program. We are glad that some residency programs apparently have moved beyond the problems we outlined, but we think that too many other programs have not reached this desirable state. For example, shortly before the publication of our paper, one of the authors had the experience of having a young male psychiatric faculty member comment to her: "I don't see why we're taking so many women into our training program when we're not geared up for them." He was referring to the fact that, for the first time in the program's considerable history, women constituted 50% of the total number of residents accepted.

To further pursue the ideas formulated in the published paper and the APA panel, a limited pilot survey of residents was conducted in 1976–1977. It indicated that the problems are still very much a part of the residency scene. Some of the preliminary results of this survey were reported in two panels at the 1977 APA annual meeting in Toronto—"The Pregnant Therapist" and "The Woman Hospital Psychiatrist."

Roles and Responsibilities of Psychiatry

SIR: In "The Psychiatrist's Responsibility and the Public Trust" (February 1978 issue) Peter Bourne, M.D., outlined the current dilemma in American psychiatry so well that I was shocked to see him lose his perspective and line of reasoning toward the end of the paper. He said, "The major challenge to psychiatry in the next decade is to make our skills available to all Americans" (p. 176). Is this not as gran-

diose and unreasonable as our accepting the burden of changing society, for which Dr. Bourne castigated us severely?

The training of paraprofessionals is a loaded issue. Why do we not train adequate psychiatrists, if we are the specialists in human behavior and the physicians of mental illness? Do we need psychiatrists' assistants? If so, then let us train and supervise them. Let us define the roles of mental health paraprofessionals and pay them adequately.

The comparison of psychiatrists with Rolls Royce craftsman when Fords are needed is a sign of the degradation to the "marketing personality." If 30% of the population needs treatment, then it needs expert treatment, not assistance. If the remaining 70% need help in ordering their lives, then experts in causes for disordered lives should be called in.

When our special body of knowledge exposes the psychopathology rampant in this country, will we be accepted? I am all for a definition of our role and skills. Would Dr. Bourne start the ball rolling?

HELEN STEIN, M.D.
Fresno, Calif.

Dr. Bourne Replies

SIR: Unfortunately, Dr. Stein's concern arises from a misinterpretation of what I said in my article. The statement "The major challenge to psychiatry in the next decade is to make our skills available to all Americans" was not meant to imply that we should train everyone in psychiatric skills. Perhaps I should have said (for greater clarity) that we should try to make our services available to the largest possible number of Americans. This would mean reducing the financial barriers to care, perhaps through national health insurance; training additional psychiatrists; and increasing the involvement of psychologists, psychiatric social workers, and family physicians in areas that do not require psychiatrists. Presumably this would make psychiatrists more available to a larger number of people. Obviously, paraprofessionals can play an important role if they have appropriate training and supervision.

PETER G. BOURNE, M.D.
Washington, D.C.

Dealing with Patients' Suicides

SIR: I would like to comment on the article "Patient Suicide as Part of Psychiatric Residency" by Ralph F. Henn, M.D. (June 1978 issue).

I agree with the author that patient suicide is not an infrequent occurrence during a psychiatric residency. One survey of a university psychiatric residency program indicated that 16% of all residents had had a patient who committed suicide (1). Although this is lower than the figures quoted by the author, it is nevertheless a significant percentage.

The author states that professional "survivor victims" had "bitterness and torment." I would like to share one method of dealing with this. When I was a resident, I was one of four trainees who had a patient commit suicide within a 2-month period. We met together for almost a year to deal with the trauma. We found that the experience of a patient suicide left each of us with feelings of embarrassment, guilt, and self-doubt. We were embarrassed because we felt that we were at fault and that patients of competent trainees and competent psychiatrists did not commit suicide. Some of us felt that we would be afraid ever to see a suicidal patient again. Initially we had each felt alone in our experience. Fortunately, we became aware that we were not unique and decided to meet as a group. Through our group meetings we were able to support each other and work through many of our feelings about the suicide (2).

I would suggest that since this is a common experience in psychiatric residencies, openness be encouraged so that when residents do have patients who commit suicide, they can meet in groups that involve self-examination in a supportive atmosphere. This may help alleviate the pain and loneliness of the experience. In addition, working through feelings about a patient suicide can allow the resident to continue to grow professionally, and to become willing to treat other suicidal patients.

Anthropological Cross-Fertilization

SIR: We enjoyed the excellent paper "Overview: Foundations of Cultural Psychiatry" by Armando R. Favazza, M.D., and Mary Oman, M.A. (March 1978 issue).

There have been several attempts to meld psychiatry and anthropology into an interdisciplinary frame of reference. Although these efforts have met with general approval from both fields, there has been insufficient use and follow-through of the extremely important cross-fertilization resulting from such collaboration.

We believe much can be achieved by intimate teamwork between a psychiatrist and an anthropologist or ethologist. Dr. Favazza and Ms. Oman have attempted to cover the broad range of mutually beneficial exchanges and are to be congratulated on their thorough job. We should, however, like to add to their list two areas in which we ourselves have been working.

We have investigated the persistence in humans of phylogenetically embedded response systems that are no longer adaptive, the circumstances that lead to their activation, and their potential to emerge as psychoneurotic, psychophysiological, or psychosomatic disturbances. This frame of reference provides a biological basis that lends itself to incorporation into a medical model without requiring one to resort to metapsychological concepts. It also provides a biological basis for some psychodynamic formulations (1).

We also believe that an unexpected bonus for anthropology is available from psychiatry. Some of these behavioral "fossils" can provide material to aid our understanding of the social interactions of the precursors of homo sapiens. In many instances such behavioral vestiges provide clues that are as valuable as anatomical ones in deciphering the stages

of human emergence (2). For instance, the biological anomaly of a 4:1 ratio of male to female dyslexics and a 2:1 ratio of male to female infant vulnerability of the brain to febrile convulsions, among other clues, set us on a path to radically new ideas about the origin of language (3). Additionally, ethological insights about the nature of existing mother-infant releaser-response mechanisms shed light on the initial emergence of language primarily as a reinforcer of mother-infant bonding behavior rather than a vehicle for communication. We also think that certain features of schizophrenia may represent an earlier biological norm (4).

A helpful fallout of these theoretical investigations has been the enrichment of psychotherapeutic procedures through biologically based psychodynamic understanding (5, 6).

A. DAVID JONAS, M.D., M.R.C. PSYCH.
DORIS F. JONAS
London, England

Dr. Favazza and Ms. Oman Reply

SIR: The team of A. David Jonas, a psychiatrist, and Doris F. Jonas, an anthropologist, has produced a series of interesting papers that place human behavior patterns in an evolutionary and ethological context. For example, in their paper on schizophrenia they write,

> Paranoid ideation is readily comprehensible when we remember that almost all animals in their natural surroundings remain constantly on the alert for possible danger at all hours of the day and all the days of their lives, so that it is not surprising that we human beings retain a sense of being on guard against menace from the environment, even if this menace be figurative.

Even though ours was an overview paper, we were unable to include every branch of the field of cultural psychiatry. The work of the Jonases is provocative and may eventually clarify our understanding of certain aspects of human behavior. More attention might be given to their psychiatric work if they could demonstrate clearly its relevance to the resolution of everyday clinical problems. However, any attempt to reduce the "medical model" to biology alone will not be successful. Every person has a body and therefore biology is significant. But every person also has a mind, and every person lives in a society and participates in a culture. The physician who can integrate biological, psychological, social, and cultural data as they pertain to the individual patient is practicing the medical model in its truest sense.

Treating Tricyclic Overdose with Physostigmine

SIR: Tricyclic overdose is seen whenever these drugs are prescribed for depressed patients. The *Physicians' Desk Reference* (1) states, "Physostigmine Salicylate is reported to reverse symptoms of tricyclic antidepressant poisoning" (1, p. 1090). Listed in order of increasing plasma levels, these symptoms are "abnormal deep tendon reflexes, unconsciousness, respiratory support, ventricular rate ≥120/min., QRS duration ≥100 msec., cardiac arrhythmias, bundle branch block, cardiac arrest, seizures and death" (2).

A 25-year-old woman took a questionable amount of amitriptyline, and the drug showed on the toxicology report. When she came to the ward her pupils were nonreactive, she showed no response to verbal stimuli, her muscles were flaccid, and the nail beds were cyanotic. Blood pressure was 100/68, pulse 140. On a random ECG the longest recorded QRS interval was 90 milliseconds. An I.V. was started. She became progressively unconscious.

It was decided to give physostigmine. Vital signs at the time of injection were as follows: blood pressure 84/64, pulse 140, respiration 40. An immediate grand mal seizure lasting one minute was noted, followed by possible cardiac arrest. A "blue alert" was called, including use of a monitor, oxygen, and suction. The blood pressure stabilized at 152/84, but the patient remained unresponsive, and a second injection of physostigmine was administered. This was followed 10 minutes later by a second convulsion.

No more physostigmine was given. The patient was treated with Lanoxin and other supportive measures and made a recovery to her pretoxic mental status in about 2 days.

Verbal contact with D. G. Spiker of Western Pennsylvania Psychiatric Institute leads me to believe that the physostigmine injections caused the two grand mal convulsions. As Spiker has written, "Whenever medication is used, care must be taken to understand the exact physiological mechanism that is to be altered by the drugs, and efforts must be made to avoid potentially fatal iatrogenic drug interactions" (3).

On Assessing the Usefulness of the PANESS

SIR: I found the Clinical and Research Report entitled "Clinical Usefulness of the NIMH Physical and Neurologi-

cal Examination for Soft Signs" by Janet A. Camp, M.Phil., and associates (March 1978 issue) particularly distressing. The readers of the *Journal* will be turned off to a diagnostic tool (PANESS) because of negative conclusions drawn by the authors on the basis of a woefully inadequate study. In fact, the only valid conclusion that can be drawn from the study is that we simply do not know the clinical usefulness of the PANESS as a diagnostic tool.

In comparing normal and hyperactive children with respect to their PANESS performance, the authors indiscriminately and without justification lumped together 56 scores representing most of the items comprising PANESS. Is it reasonable to expect that every one of 56 responses to a neurological test battery is equally discriminative of diagnostic groups, or discriminative in the same direction? This is the assumption that must underlie the authors' lumping of the subjects' test scores.

In fact, it was not necessary to lump these scores in order to make comparisons between groups. Multivariate statistical procedures permit comparisons of groups simultaneously along more than one dimension. Individual scores (items) are weighted by these procedures so that optimum separation of groups is achieved. The proper statistical procedure for the Camp and associates study is discriminant analysis or multivariate analysis of variance. In an article on "Anomalies of Motor Development in Hyperactive Boys" Denckla and Rudel (1) arrived at very different conclusions from those of Camp and associates, as an example of the application of this procedure.

Suppose we did accept the authors' use of the lumping procedure and the t test statistic as the valid method of group comparison (neither procedure is, in fact, valid). Out of the 7 age groups for which hyperactives and normals were compared, the Ns for 5 of the hyperactive groups were 2, 5, 4, 2, and 0. Reliable statistical conclusions simply cannot be drawn on the basis of such small samples using t tests. Finally, the authors did not discuss their finding of a significant difference in the opposite direction from that predicted. It may be an artifact of the multiple t test procedure (some significant differences can be expected by chance when many t test comparisons are made), but at least it should have caused the authors to pause and consider the validity of their approach to the validation of the PANESS.

MELINDA BROMAN, PH.D.
New York, N.Y.

Ms. Camp and Dr. Bialer Reply

SIR: Dr. Broman's statement that "the only valid conclusion . . . is that we simply do not know the clinical usefulness of the PANESS as a diagnostic tool" is precisely the point of our paper, as was clearly stated in our last paragraph. Our intent *was* in fact to "turn off" psychiatrists from using the PANESS as a diagnostic tool until its validity is demonstrated. Our data, in conjunction with those of Werry and Aman (1), are meant to caution physicians against accepting this instrument prematurely.

The PANESS is a first attempt at a standardized soft sign examination and is intended to be administered in its entirety. Our purpose was not to modify the instrument but to ascertain its diagnostic utility. Obviously, not all items discriminate equally well, as an initial stepwise multiple regression analysis of our data indicated. However, items that do discriminate would of necessity raise the total scores of hyperkinetic children. The PANESS items represent a cross-section of typical soft sign examinations. Consequently, they cannot validly discriminate in the "opposite direction," as Dr. Broman suggests, since by definition an item is not considered a clinical soft sign if it is present in normal children. Thus, if the instrument were valid, the total score measure would in fact reflect the higher incidence of soft signs in hyperkinetic children.

The small sample size in a number of the hyperkinetic age level groups underscores the diagnostic problem with the PANESS. The practicing physician wishing to use the examination diagnostically is dealing with a single child. Any soft sign instrument that shows statistical differences based on large samples but cannot detect the presence of these signs in an individual case is worse than useless for diagnostic purposes. Although our study may be statistically inelegant, our findings remain both statistically and practically correct: The PANESS in its current form is an inadequate diagnostic tool for the practicing psychiatrist or pediatrician.

Postprandial ECG

SIR: I have a question regarding the article "Factors Influencing Phenothiazine-Induced ECG Changes" (January 1978 issue) by Henry A. Nasrallah, M.D. Should not the "obvious implications" of the provocative effect of food intake be that the ECG should be done postprandially at a time when the blood glucose level is likely to be maximal? Under these conditions, which are analogous to the glucose tolerance test in diabetes, any risk to the patient from a food-drug interaction would probably be revealed.

A.A. SCHIFF, M.R.C.S.
Twickenham, England

Dr. Nasrallah Replies

SIR: A fasting pretreatment ECG remains the best baseline measurement with which to compare subsequent ECGs, whether postprandial, posttreatment, or both. If the intent is to observe the phenothiazine effects alone, then the posttreatment ECG must be measured in the fasting state.

Both food intake and phenothiazine treatment can produce benign ECG changes that are reversible by an overnight fast (1, 2). An increase in intracellular-extracellular K^+ ratio has been suggested to mediate both (3). Thus, Dr. Schiff's suggestion is well taken in that the occurrence of ECG changes postprandially before phenothiazine treatment

might be predictive of similar ECG changes after phenothiazine treatment. However, I believe that the overnight fast is more useful in detecting persistent ECG abnormalities, which, if not reversed by K^+ intake (4), can portend higher risk for phenothiazine-induced arrhythmias.

Cardiovascular Excitability and Emotional Stress

SIR: In his article "Emotional Causes of Sudden Death" (December 1977 issue) Joel E. Dimsdale, M.D., reviewed several papers which showed that the cardiovascular system may respond to emotional stress in an unfavorable way even in healthy individuals.

Our studies of attitude change in neurotic patients under different degrees of emotional arousal yielded a result that may have some relevance to Dr. Dimsdale's article. We discussed therapeutically relevant topics with patients who were artificially aroused through inhalation of adrenaline. We found that these patients exhibited significantly greater cardiac lability when those topics were introduced in a subsequent drug-free session than did patients who had been treated in the same way but with a placebo inhalant (1).

This finding suggests that a person can be conditioned to a state of heightened cardiovascular excitability by a topic even if this state was originally triggered by a different mechanism and only accidentally became associated with the topic. Therefore, it is possible that those persons who experience frequent stressful situations develop excitatory cardiovascular responses not only to the actual stress situations, but coincidentally to other situations which had only minimally affected the autonomic nervous system. In such cases, the resulting damage to the cardiovascular system could greatly exceed the amount expected from the summation of the individual stress situations.

RUDOLF HOEHN-SARIC, M.D.
Baltimore, Md.

Dr. Dimsdale Replies

SIR: I appreciate Dr. Hoehn-Saric's calling his work to my attention. The evidence relating emotional factors to heart disease is, as I indicated in my review, particularly compelling because of the convergence of findings from different approaches. The major thrust of Dr. Hoehn-Saric's work was to investigate attitude change in psychiatric patients who were exposed to physiological arousal by adrenaline inhalation (1). A serendipitous but important finding was that combining adrenaline inhalation with discussion of therapeutically relevant topics resulted in the patient's "learning" a response of autonomic arousal when later confronted with the same topics. This arousal was manifested by significant changes in heart rate variability while the patient was discussing the focal topic, even when no adrenaline was inhaled.

This work is a logical progression of one of the studies quoted in my review. Newton and Gantt (2) demonstrated in dogs that a persistent change in heart rate could be learned after a single conditioning situation.

We tend to regard the autonomic nervous system response to emotion as an automatic consequence of arousal as opposed to a learned response. Recent work on conditioning the autonomic nervous system (3) is frequently perceived as a radical innovation in normal physiology. The intriguing implication of Hoehn-Saric's work is that such "learning" in the autonomic nervous system is the norm, not the exception, that biofeedback occurs in daily life.

Prescription Drug-Induced Organic Brain Syndrome

SIR: We were very interested in the Clinical and Research Report "Prescription Drug-Induced Organic Brain Syndrome" by Toshihiko Maruta, M.D. (March 1978 issue) because we were recently baffled by a similar case.

A 37-year-old truck driver was transferred to our hospital from another psychiatric facility for a full neurological workup and further psychiatric care. He had been at the other facility for approximately two months and had been ill for two months before that. The main symptoms of his illness were sudden work avoidance (with a record of 15 years with the same company), withdrawal, crying spells, episodes of staying in bed, and, finally, suicide threats, which prompted his involuntary hospitalization. Over this four-month period (two as a private psychiatric outpatient and two as an inpatient), the patient had received a total of nine different medications—tranylcypromine, imipramine, desipramine, amitriptyline, perphenazine, chlorpromazine, haloperidol, flurazepam, and biperiden—at different times, with no change in his condition. In fact, before he was transferred to our unit, the patient had had decreased mobility, slurred speech, marked blepharospasm, loss of tongue movement, left facial weakness, confusion, disorientation, and decreased cognitive functioning. In short, he was believed to have had a cerebro-vascular accident. Prior to his symptoms that began

five months earlier, this patient had never visited a psychiatrist or shown symptoms indicating that he should.

Under our care, the patient was taken off all drug therapy, which at that time consisted of haloperidol, desipramine, and biperiden. The results of the neurological workup, which included electroencephalography, skull series, brain scan, and CAT scan, were all negative except for the EEG, which showed some focal slowing of the postereotemporal and occipital regions on the left. The patient began to improve, showing normal mobility, more spontaneous coherent speech, increased interest in himself and his surroundings, and general improvement in his cognitive functioning. A series of three more EEGs was done over the ensuing 22 days with a gradual return to normalcy by the time the last one was done. The patient maintained his improvement, and was discharged without medications on the 24th hospitalization day. Three weeks later he was back at work.

This patient may well have undergone the full episode of depression with return to mental health despite all treatment; however, we feel that the prescription drugs, especially the use of polypharmacy, clouded and augmented his illness. This points out the necessity for regular review of medications and the justifications for them.

Psychopathology of the Team Concept

SIR: I would like to comment and expand on a point discussed in the article "Becoming an Administrator: The Vicissitudes of Middle Management in Mental Health Organizations" (March 1978 issue) by David M. Dressler, M.D.

The treatment team, which should be or once was a useful therapeutic modality in psychiatry, has been misused, distorted, and politically exploited. As with other therapeutic modalities, the improper use of the team concept can have detrimental, or even fatal, side effects.

In a treatment facility like Napa State Hospital, the members of the treatment team are the psychiatric technician, social worker, psychologist, rehabilitation therapist, occupational therapist, and other lay personnel. The ward psychiatrist or physician then acts as supervisor of the treatment team. However, the supervisory capacity of the psychiatrist has been undermined by the use of vague terminology such as "member of . . ." or "consultant to the treatment team." The function of the physician has been further confused by PRU 57, which does not adequately define the roles of administrators or team leaders when they are nonmedical professionals. Moreover, the addition of the "team leader" (based on the "herd" concept of the social scientist; that is, the strongest in the herd is the leader) has further obscured the supervisory role of the psychiatrist. Unfortunately, the homogenous "wild herd" does not have specialty members or licensure restrictions.

There are many ways in which the treatment team can become pathologic. The psychiatrist may merge imperceptibly with the treatment team and lose his identity. When this happens, the psychiatrist can no longer function to monitor psychiatric treatment. Conversely, the team members may lose their identities. There is overlapping of the roles of the various disciplines, or there is blurring or loss of ego boundaries. (The team members begin to respond to stimuli within the team rather than to external stimuli—that is, to the patient, who can no longer be viewed objectively.) This resembles the autistic thinking of the psychotic. Reality testing has become impaired.

The team member may fail, by omission or commission, to give the feedback of his own specialty or discipline. The team member may cross boundaries and dominate other disciplines, suppressing important feedback from those disciplines, thus misleading the team. It is here that the monitory capacity of the psychiatrist or ward physician should come in.

With regard to the team leader, the position of coordinator can be misused, and a supervisory and decision-making position be assumed. When a nonphysician team leader starts making decisions for the group, the danger of pathological decisions exists, especially if the process cannot be controlled by the supervisory capacity of the psychiatrist.

The psychiatrist's or ward physician's supervisory role has been blurred by the addition of the team leader and lay administrator. This has weakened and confused the physician's supervisory role. Is this a political maneuver of the paramedical workers to gain control and power in the mental health field? When the physician is a weak supervisor, he can easily be overruled by a strong team leader or the rest of the treatment team. Pathologic coalition and conniving cannot be halted if the psychiatrist is given one vote in the treatment team. On the other hand, the treatment team can be addicting to the physician; more and more he relies on the treatment team and no longer uses his discretion, ignoring even his legal responsibilities.

When the psychiatrist or ward physician becomes too dominant, he may suppress the initiative, enthusiasm, and motivation of the team members. In order to avoid this situation, it would be advantageous to have another psychiatrist or physician available for consultation. However, with PRU 57, the physicians have been so isolated from each other, especially under nonmedical program directors, that there is no mechanism for mutual feedback and peer review. Is this another political exploitation of the system?

The addition of lay administrators, which is due to the lack of doctors, has made the team concept more complex. The original purpose of the lay administrator was to assist the physician in his administrative duties so that the physician could devote more time to clinical work. PRU 57 has allowed the lay administrator to supervise psychiatric technicians, social workers, psychologists, and rehabilitation therapists. This supervisory capacity has been misused and has now extended to the treatment team and to the physician. Occasionally, lay administrators have even overruled the team decisions and the clinical decisions of the physician. The lay administrator may become a dictator in his own program, ignoring the treatment needs of the patient.

Another difficulty is that the educational background of the lay administrator may not be adequate to allow him to perform peer review of some of the professionals he supervises. For example, a program director who is a social worker cannot perform peer review for a psychologist. The system becomes more implausible when the nonmedical program director has no one to review his work: PRU 57 has no built-in mechanism to review the program director's work.

The only solution to the problems of the pathologic treatment team is to start redefining roles of various treatment team members. As for PRU 57, it should be either revised or discarded.

MARIANO A. FAVIS, JR., M.D.
Napa, Calif.

Dr. Dressler Replies

SIR: The letter by Dr. Favis raises important issues concerning the design and operation of clinical management teams and, more importantly, the role of psychiatrists in multidisciplinary organizations. The team concept can be extremely valuable when patients have multiple problems and when organizations are structurally complex, with many staff members and diverse decentralized programs. Although the leader of the team need not be a psychiatrist, his role relationship to team members and the sponsoring organization needs to be clearly and appropriately defined with respect to level of responsibility and authority (1). The psychiatrist may serve as a primary care clinician, medical back-up physician, team leader, clinical supervisor, or consultant. Although he may function in more than one capacity, vague or contradictory role definitions lead to ineffective team functioning, which ultimately has an adverse effect on the quality of patient care.

The role of psychiatrists in mental health organizations is undergoing significant change at the present time. Other professional disciplines are demanding a more significant role in decision-making processes affecting patient care, thereby challenging the traditional autonomous prerogatives of the psychiatrist. Although these changes may be to some extent both reasonable and appropriate, the psychiatrist will gradually lose his central position as a health care provider unless he is willing to assume positions of significant responsibility in mental health organizations. Unfortunately, consumer pressures and governmental regulations seem to be opposing this objective. Improved public relations on the part of concerned groups such as APA and increased emphasis on mental health administration in residency training programs may help to reverse this trend.

Usefulness of Lithium for Aggressiveness

SIR: Four years ago I published a report on the usefulness of lithium in aggressive prisoners (1). However, subsequent clinical reports have attested to the effectiveness of lithium in preventing aggressive outbursts (2, 3). The composition of groups studied has varied, including subjects with chronic psychosis, personality disorder, brain injury, and epilepsy. Furthermore, aggressive children with various diagnoses have been noted to improve with lithium administration. In the face of an array of clinical diagnoses, common underlying features have been suggested and include 1) undiagnosed, atypical affective disorder, 2) family history of affective illness, and 3) affective elements apparent in the illness. Traditional diagnosis alone will not be enough, nor is a description centered on affective illness likely to be complete. Rather, I would suggest that there is a common underlying neuropsychological disturbance which is behaviorally manifested in the following ways: 1) extreme stimulus sensitivity—a "hairtrigger," 2) the inability to reflect on the meaning or intent of the stimulus, i.e., the lack of reflective, introspective review to assess accidental or purposeful attack, and 3) maximal response—little capacity to modulate the expression of anger.

In cases I have seen, the absence of the capacity for reflective consideration of the meaning of the stimulus seems to be most important. After lithium was given the person still retained some stimulus sensitivity, although it was reduced, and could on occasion be angry and even violent. However, the intervening step of reflective consideration of the appropriateness of a violent response had been strengthened, allowing the person to constructively review the nature and setting of the stimulus.

Since these three characteristics do not imply any psychiatric diagnosis per se, they form a behavioral triad that may be worthy of further investigation and may be useful in identifying these individuals with explosive violence who might benefit from lithium. Furthermore, these descriptions may suggest a basic strategy for study of these explosively violent individuals.

I offer these suggestions not as a final definition of a lithium-responsive, violent population but rather as a point for future investigation in this important area.

Correction

In "Obesity and Psychoanalysis" by Colleen Rand, Ph.D., and Albert J. Stunkard, M.D., in the May 1978 issue, the last sentence of the precis is incorrect. The decrease in the percentage of obese patients suffering from body image disparagement was from 40% to 14%. Also, in the section Body Image Disparagement, the second sentence of the second paragraph should read, "Twenty-nine obese patients reported severe and 35 mild body image disparagement. . . ."

There was an error in the reference list for "Sudden Infant Death Syndrome: Impact on Families and a Direction for Change" by Stanley E. Weinstein, M.S.W., in the July 1978 issue. Reference 4 should be "Bergman AB: A Study in the Management of Sudden Infant Death Syndrome in the United States. Seattle, Children's Orthopedic Hospital and Medical Center and the University of Washington School of Public Health and Community Medicine, 1973, p 11."

The Official Actions section of the August 1978 issue (p. 1028) carried the heading "The American Board of Psychiatry and Neurology Commission on Certification in Administrative Psychiatry." The Commission on Certification in Administrative Psychiatry is not part of the American Board of Psychiatry and Neurology but a component of the American Psychiatric Association.

The staff regrets these errors.

BOOK REVIEWS

Psychopharmacology: A Generation of Progress, *edited by Morris A. Lipton, Alberto DiMascio, and Keith F. Killam. New York, N.Y., Raven Press, 1978, 1,731 pp., $49.50.*

The purpose of this all-encompassing volume is well stated in its preface, which notes that it was developed by the American College of Neuropsychopharmacology for the purpose of providing a comprehensive survey of progress in that field. The reader who even scans the book will see that it performs this function particularly well.

Even a glance at the contents reminds us of the inroads the relatively new science of neuropsychopharmacology has made. To most of us it is a reminder that we have much—very much—to learn if we are to be competent in the understanding and use of these agents. The psychotropic drugs burst on the scene less than a quarter of a century ago, and for many psychiatrists their use for a while was empirical. There is no longer an excuse for this; the user now is required to be well acquainted with the uses and the possible abuses of these pharmacological agents. The drugs in question were the first really effective additions to the psychiatrist's therapeutic armamentarium. They are powerful agents, and expertise is required in their use lest the last condition of the patient be worse than the first.

The entire field is covered in this volume, beginning with the ethics of the use of the drugs, their biochemical bases, and their clinical utilization. Next, the mechanism of their action is reviewed on a basic molecular level, and the known biochemical and pharmacological actions involved in initiating or regulating neuronal transmission are explained.

Data are presented on the use and the role of psychotropic drugs in the overall treatment program for various categories of emotionally and mentally ill patients. No excessive claims are made for these medications, individual variations in responses to them are recognized, and some reasons are suggested for their actions.

Even to mention the subheadings in this extensive volume would require more space than we have here at our disposal. Starting with a historical overview by the editors and followed by a chapter titled "In the Service of Psychopharmacology Research: The Psychopharmacology Service Center-Psychopharmacology Research Branch (NIMH) Program 1956–1976" by Jerome Levine, the chapters follow as they should, i.e., "Strategies of Basic Research" by Seymour Kety and "Strategies in Clinical Psychopharmacology" by Heinz Lehmann. The mention of the names of these authors and those of other chapters in the section titled Neuroanatomical, Histochemical, and Neurophysiological Mechanisms of Drug Action would convince the reader that he or she is being instructed by experts.

The final segment of the book considers a few of the hazards associated with these powerful new agents along with a consideration of drugs that have been around for a long time and are often subject to misuse. A chapter on "Opiate Receptors and Opioid Peptides: A Ten-Year Overview" by Avram Goldstein is worthy of special note, as is a chapter on "Cannabis: A Review of Progress," by Louis Harris. The neurophysiology and neurochemistry of barbiturates and alcohol are reviewed by Michiko Okamoto.

Nancy Mello gives an authoritative statement on "Alcoholism and the Behavioral Pharmacology of Alcohol: 1967–1977," and Roger Meyer discusses the "Behavioral Pharmacology of Marihuana." Both of these are especially well done, but the same can be said of most of the other chapters. Apparently, nothing that has to do with psychopharmacology was forgotten. A reviewer is at his wit's end trying to even mention some of the excellent material contained in the volume. Pediatric psychopharmacology, geriatric psychopharmacology—you name it, it is all here, with notable stops to discuss clinical research, drug assessments, toxicology, and side effects. Taken together, a review of the subjects covered in this book would necessitate another volume of similar heft (1,731 pages!).

One thing I am sure of—the completeness of the work. It definitely encompasses a "generation of progress." It is a reference book that will be consulted for years to come. I can also state without fear of contradiction that no library concerned with any aspect of pharmacology would be complete without it. It was a prodigious task to get materials and authors together and properly orchestrate them. All concerned should be complimented. The volume is enthusiastically recommended.

F.J.B.

Adaptation to Life, *by George E. Vaillant. Boston, Mass., Little, Brown and Co., 1977, 396 pp., $9.95.*

This book describes the results of a 30-year follow-up study of adult development. The study began in 1938, when the men studied were college students at Harvard University. Dr. Vaillant has been able to follow 95 of the original 268 subjects. These men were interviewed approximately 30 years after they started college in the late 1930s and early 1940s. Dr. Vaillant had access to all of the information that was collected during the subjects' college years and during the intervening years, but most of the book is dedicated to describing his own follow-up interviews.

Dr. Vaillant followed his subjects literally to the four corners of the United States. These are fascinating men who comprise the upper crust of our society. Each has his own individual pattern of development, making it impossible to group them by types. They have characteristics that make them, at times, interesting, creative, intelligent, open-minded, and invigorating. At other times they come across as depressed, pathetic, prejudiced, and full of psychopathology. Obviously, they represent a continuous mixture of all of the above.

The book is aimed at the psychologically aware and intelligent reader. It presents, in the best of Robert White's *Lives in Progress* (1) tradition, the complexity of man and his

internal and external environments. It is extremely well written, flows easily, and presents the people whom Dr. Vaillant studied well and with little jargon. I believe that at times Dr. Vaillant's fear of alienating the intelligent public runs away with him. For example, he describes the two defense mechanisms of dissociation and projection used by one of his subjects and adds, "These *clumsy* psychiatric terms are defined in Appendix A; in this chapter, argot will be translated into English" (p. 16; my italics).

The book's major weakness is also its strength. It presents the lives of these Harvard men well, in readable fashion, and makes one believe that what happens in childhood counts later in life. Its weakness lies in the fact that there is no serious attempt to discuss the study's findings in the general context of the behavioral and social sciences. The scholarly review is weak, and the discussion of concepts of mental health is one-sided, value-laden, and superficial.

Dr. Vaillant seems to shy away from any serious attempt to validate his clinical observations by the usual methods of rating scales, psychological testing, pencil and paper tests, ratings of the interviews, or behavioral observations of others (e.g., spouses). He is obviously familiar with these psychological techniques, and he had enough subjects to make the use of other observational methods possible. I do not know why he elected not to do so. I believe that scientifically (from my biased perspective), it would have made *Adaptation to Life* a better book. One simple rating that would have been interesting is the self-rating of the interviewer of the subjects (Dr. Vaillant). It seems to me that what is called counter-transference in the therapeutic area ran rampant through the interviews. Ratings such as "How likable was the subject?" and "How warm, distant, anxious, depressed, confused, fatherly, motherly, the interviewer felt toward his subjects right after the interview and a week later" would have helped to objectify the observations. The lack of an index adds to the feeling that this is not a scientific treatise.

Returning full circle to my earlier statement, the above weakness might have strengthened the book for certain readers. It is easy to recommend Dr. Vaillant's book to anyone interested in the developmental psychology of adults. It is a worthwhile addition to the literature, and it is exceptionally well written.

DANIEL OFFER, M.D.
Chicago, Ill.

Clinical Psychopharmacology, *edited by Jerrold G. Bernstein, M.D. Littleton, Mass., PSG Publishing Co., 1978, 154 pp., $20.00.*

During the past decade a plethora of books on psychopharmacology have appeared. They vary from excellent textbooks to volumes summarizing and elucidating relevant psychopharmacological research to practical workbooks for the busy clinician (1–3). This small volume is a compilation of papers presented at a symposium held in Boston. Dr. Bernstein has done a fine job in editing this volume; all of the chapters are very readable and hold the reader's interest throughout.

The book begins with an overview of the biological basis of mental illness by Seymour Kety. Dr. Kety takes a historical tour through the findings that form the biological basis of psychiatry. He surveys both genetic and chemical data to demonstrate that mental illness has organic determinants, but he does not lose the reader in technical biochemical formulations.

Dr. Jonathan Cole's chapter on antianxiety drugs also reviews the biochemical basis of these medications. He explains how animal models are used to test the properties of antianxiety drugs. Clinicians who use minor tranquilizers should be aware of the laboratory basis for studying the behavioral properties of these medications. Although there are many references to comparison of these medications with placebo effects, one omission in this volume involves the specific issues of placebo phenomena. Dr. Cole ends his chapter with a clinical reminder of the often forgotten noxious effects of minor tranquilizers. An unusual side effect of benzodiazepines, for example, is hostile, irritable behavior.

David Greenblatt's chapter on insomnia is complemented by useful, easy-to-read tables. He provides a nice overview of the medical and psychiatric causes of sleep disturbance. He also clearly discusses the various advantages and difficulties of commonly used hypnotics. One area not covered is how to take a careful sleep history to rule out such other sleep disorders as sleep apnea and narcolepsy (4).

Dr. Bernstein's chapter on the chemotherapy of psychosis provides an overview of neuroleptic medication. He offers facts about the side effects of these medications and outlines the various phases of antipsychotic drug treatment of severely ill psychiatric patients. Dr. Alberto DiMascio's chapter on long-acting psychotropic drugs complements the previous chapter on the acute psychoses.

Dr. Gerald Klerman's contribution on the psychopharmacological treatment of depression is very interesting. He discusses the incidence of depression and especially the increased frequency of this disorder in women. His brief discussion of available treatments for mood disorders provides a balanced overview of psychological, social, and organic interventions. Dr. Bernard Levy's discussion of atypical manic-depressive illness takes into account Adolf Meyer's observation that manic-depressive disease has a multifaceted presentation. Excellent clinical examples of syndromes of acute psychosis in adolescence, recurrent paranoid psychosis, and recurrent depressions in very successful individuals remind the reader that bipolar illness can occur in various forms. Dr. Keith Conner and Dr. Rachel Gittelman-Klein provide two chapters on psychopharmacology of children. Their chapters overlap in content but provide information about the approach to the pharmacological treatment of childhood disorders, with emphasis on childhood depressions as well as hyperkinetic phenomena.

A chapter on the medical aspects of psychotropic drugs includes commonly seen side effects of these medications. Part of the difficulty with publishing a book on psychopharmacology is the rapid advancement of knowledge in this field. This chapter is already outdated because of a recent study by Burckhardt and associates (5) showing a persistent at-rest tachycardia in patients receiving tricyclic medication. However, the data provided in this chapter are generally useful to clinicians. It would have been helpful if information about the hepatotoxic effects of these medications had been included. The book concludes with chapters on drug abuse and its management and a brief statement on the patient's right to know about psychotropic medications.

This book provides an opportunity to refresh one's general knowledge about psychopharmacology. However, it could

have given over more space to the approach to diagnosis of psychiatric conditions. Without the ability to diagnose, rational treatment is often difficult. Another useful addition would be a further discussion of Donald Klein's approaches to anxiety and depression (6). Despite these omissions, this book would be useful for nonpsychiatric physicians, for psychiatrists who rarely use medication, and for other health professionals who are interested in psychopharmacology. Its readability and size also make it useful for medical students.

Research on the Effects of Television Advertising on Children: A Review of the Literature and Recommendations for Future Research. Report Prepared for the National Science Foundation and Research Applied to National Needs (RANN). *Washington, D.C., U.S. Government Printing Office, 1977, 229 pp., $3.75 (paper).*

This is an extensive and quite technical research report summarizing the present state of research and knowledge regarding television advertising as it affects children. It recommends a plan of future research on the subject. A definitive verdict about the effects of television advertising on children is disclaimed, but any intelligent reader will draw some conclusions from the material presented.

Questions about the effects of television on children have concerned professionals and parents for the last two decades. Considerably more attention has been given to the effects of television violence on children, at least in journals directed toward health professionals. Articles on the subject of violence are numerous and often impassioned—rightfully so, since statistics document the fact that by the time they have graduated from high school most children will have spent more time in front of the television set than in school. Television has become one of the dominant forces affecting development, acculturation, and learning of society's moral and ethical values.

This report suggests four fundamental concerns that have to do with whether the products advertised on television are safe, whether the vulnerability of children is exploited, whether the specific techniques used are deceptive or misleading to children, and whether the culmulative exposure may adversely affect development. As is usual, three groups are involved in the debate: industry, government, and consumer organizations. The report points out that relations among these groups have often been contentious. Both industry and consumer groups attack the government, but industry tends to complain of too much government interference, while consumer groups tend to complain of too much timidity on the part of governmental agencies. The consumer groups also believe that industry is less concerned with the possible harm to children than with selling advertising, while industry accuses the consumer groups of being self-appointed guardians who do not represent the views of the majority of parents.

By means of a questionnaire survey of interested parties, a review of the literature, and consideration of which issues were amenable to empirical testing that might also subsequently affect national policy, the research group arrived at the following list of 10 issues: 1) children's ability to distinguish television commercials from program materials, 2) the influence of format and audiovisual techniques on children's perceptions of commercial messages, 3) source effects and self-concept appeals in children's television advertising, 4) the effects of premium offers in children's television advertising, 5) violence and unsafe acts in television commercials directed toward children, 6) the impact on children of proprietary medicine advertising, 7) the effects on children of television food advertising, 8) the effects of volume and repetition of television commercials, 9) the impact of television advertising on consumer socialization, and 10) television advertising and parent-child relations.

A chapter of the report is devoted to each of these issues, and these chapters become the substance of the report. Although the chapters vary in length from 6 to 18 pages, each consists of an introduction, a discussion of the current regulations, a discussion of incidence, a discussion of research evidence, a summary, and, finally, recommendations for additional research. Thus, although the report is probably overly detailed for most readers who have some interest in the subject, its structure makes it easy to absorb the general ideas without dwelling on all of the particulars.

In formulating their recommendations for future research the authors believe that three levels of action are necessary: one to test specific hypotheses, another to document how children perceive actual individual commercials, and a third to better understand the role of television in children's lives. "Ultimately," they conclude, "the research should lead to creation of standardized measures for testing commercials to insure that they are truthful, accurate, and fair to children's perceptions."

The remainder of the report consists of a technical evaluation of 21 primary empirical studies of television advertising. A statistical summary of the responses to the survey questionnaire mentioned above is included. Official guidelines are reproduced as they pertain to children. Finally, an extensive bibliography is offered for those who might want to read in more detail on certain aspects of the report.

This report will be of particular interest to mental health professionals who deal with children, especially those interested in child development, child rearing, parent education, and primary prevention of mental disorders.

JOSEPH M. GREEN, M.D.
Madison, Wis.

Respectful Treatment: The Human Side of Medical Care, *by Martin R. Lipp, M.D. Hagerstown, Md., Harper & Row Medical Department, 1977, 222 pp., $11.50 (paper).*

Respect is the most important value in human relationships. Everyone knows what is meant by self-respect and

respect for others, but both concepts are hard to define. The author wryly quotes H.L. Mencken's cynical definition of self-respect as "the secure feeling that no one, as yet, is suspicious." Dictionaries have trouble defining the term. The *Concise Oxford* misses the target ("regard with deference, esteem, or honor") and becomes more meaningful only when the definition is made operational ("avoid degrading or insulting or injuring or interfering with or interrupting, treat with consideration, spare, refrain from offending or corrupting or tempting"). Perhaps the Declaration of Independence comes nearest to capturing the meaning. "All men are born equal" may be untrue except as a political ideal or as an article of faith, but respect implies a sense of basic human equality.

Lipp's short book is a highly successful attempt to assist the physician in making operational his or her respect for the patient, and particularly for patients of psychiatrists in a general teaching hospital. The author is intimately familiar not only with acute psychiatric wards but with all those parts of a good teaching hospital in which psychiatric advice is sought—major surgical wards, special care units, dialysis units, oncology wards, and emergency departments. He writes with a firm grasp of the philosophical, theoretical, and practical issues that confront the physician assisting in the treatment of grossly disabled or disfigured persons, chronically or terminally ill patients, and "problem patients" of every variety—unreasonable, angry, petulant, overly affectionate, addicted, psychotic, suicidal, and violent.

There is a valuable chapter on the family of the patient, and a final chapter (very practically written) concerning the necessity of the physician's having self-respect and the "occupational hazards of physicianhood." The section on psychotherapy and counseling initially ruffled my feathers, but after rereading I found no quarrel with it. The relationship between any physician and his or her patient is the powerful vehicle of all treatment, and the variously labeled psychotherapies enhance that power in critically important ways—yet only weakly.

The book's title is apt to be misleading, suggesting another motherhood sermon. Lipp even sells himself short in his preface—"My primary aim is to provide a handbook in practical psychiatry for non-psychiatrists." I would strongly recommend the book as valuable or even essential reading for all medical students and physicians, including psychiatrists of differing orientations and levels of experience. It is certainly a must for any psychiatrist working as a consultant in an acute general hospital.

DONALD J. WATTERSON, M.D.
Vancouver, B.C., Canada

Attention, Voluntary Contraction and Event-Related Cerebral Potentials. Progress in Clinical Neurophysiology, Vol. 1, *edited by John E. Desmedt. Basel, Switzerland, S. Karger, 1977, 253 pp., $37.75.*

Auditory Evoked Potentials in Man: Psychopharmacology Correlates of Evoked Potentials. Progress in Clinical Neurophysiology, Vol. 2, *edited by John E. Desmedt. Basel, Switzerland, S. Karger, 1977, 207 pp., $37.75.*

In the last two decades a great deal of new and valuable information about brain functioning has been obtained by analyzing the evoked electrical activity recorded from the intact human scalp. This event-related brain activity has been useful in gaining a better understanding of sensory, perceptual, and cognitive processes in the human brain. More recently, the recording and analysis of evoked neuroelectric activity has provided new diagnostic capabilities to assess functional neuropathology.

The first chapter in volume 1, written by Donchin, Callaway, Cooper, Desmedt, Goff, Hillyard, and Sutton, represents basic methodological criteria for studies of evoked potentials in man. This is an important contribution that should be heeded by every worker in the field. Chapter two, by Desmedt, is also about methodological issues and is equally important. The next two chapters, by Skinner and Yingling, deal specifically with cerebral mechanisms underlying selective attention and should definitely be read by all those concerned with attentional mechanisms. The authors present a novel formulation involving a specific gating process at the thalamocortical level. This thalamocortical process interacts with a lower brain stem reflexive mechanism and results in selective filtering of sensory experience or reflexive orienting responses.

A well-written chapter on the motor and sensory determinants of slow potentials by Syndulko and Lindsley completes the section on selective attention and slow potential shifts. This chapter provides an elegant demonstration of the influence of motor and sensory factors on cortical slow potential shifts in man. Although the three papers in this section are all innovative and excellent, the section as a whole suffers from the glaring omission of chapters dealing with recent human data on the relationship between event-related potentials and attention. The rest of this volume is composed of several well-written chapters on voluntary contraction and event-related potentials.

Volume 2 presents the current state of the neurophysiological mechanisms involved in far-field and late auditory evoked potentials and their clinical uses in man. The various chapters in this section will undoubtedly become indispensable reading to all investigators in this field. The chapter by Goff and associates is an excellent paper on the neural sources of short latency components of the auditory evoked potential in man. The clinical applications of auditory evoked potentials are discussed in a number of well-written chapters (Galambos and Hecox, Starr, Rapin and Schimmel, and Peronnet and Michel). These and other chapters will be of great interest to those concerned with the use of electrophysiological techniques to assess brain dysfunction.

The last section of the book includes three chapters dealing with the effects of various drugs on evoked potentials in man. The chapter by Lader offers a rather brief but valuable discussion of the methodological difficulties encountered in using evoked potentials to assess the action of psychotropic drugs. Lewis, Dustman, and Beck's chapter provides a unique description of the acute and chronic effects of marijuana intake on cortical function. They present strong evidence for the persistent deleterious effects of chronic use of relatively small doses of marijuana. The chapter by Saletu is an excellent demonstration of the use of evoked potential techniques to conduct retrospective and prospective studies of the action of psychotropic drugs on the CNS.

These first two volumes in the series can be considered an important contribution to this area of research. However, the comprehensiveness of the material and the sequence of topics is somewhat enigmatic and leaves something to be desired. Careful attention should be devoted to the choice and logical sequence of subject matter.

At present these two volumes comprise the most current review of some of the most active areas of research dealing

with evoked brain potentials in man. As such, these books would be most valuable to researchers in these areas and to those interested in using neurophysiological techniques to study brain function or to assess brain dysfunction. These books have the additional value that most of the contributors seem to have spent time considering and elucidating the conceptual aspects of the work being performed in their areas of expertise. These two volumes make a considerable contribution to the field of human neurophysiology and provide new insights that will be of lasting value.

HENRI BEGLEITER, M.D.
Brooklyn, N.Y.

The Borderline Patient, *by Roy R. Grinker, Sr., M.D., and Beatrice Werble, Ph.D. New York, N.Y., Jason Aronson, 1977, 222 pp., $12.50.*

Ten years after the publication of *The Borderline Syndrome* (1), two of the authors of that major piece of research have come forward with its clinical companion. *The Borderline Patient,* which is based on the research of the previous book, has been supplemented by additional work undertaken in response to methodological criticism of the earlier study. It is intended "to clarify for the clinical psychiatrist what the borderline patient is and what he is not" (p. vi). The authors add, "We wished to describe individual patients so that the clinical psychiatrist could more easily diagnose his own patients and thereby know their prognosis and appropriate treatment if any" (p. 210).

In approaching the subject of the borderline patient, Grinker and Werble begin with the firm conviction that the medical model, with its emphasis on observation, clinical description, diagnosis, and classification, must constitute the foundation of the science of psychiatry. In addition, they operate with two basic assumptions about the borderline syndrome. First, they believe that schizophrenia is not equivalent to psychosis and that the concept of latent or borderline schizophrenia is not viable. Second, they believe that their earlier research established that borderline patients exhibit a group of core phenomena consisting of "developmental distortions of ego functions. These are anger as the main or only affect, a defect in attaining and maintaining affectional relationships, absence of adequate self-identity, and depressive loneliness" (p. 7).

Within this conceptual framework, the authors describe 19 patients given the diagnosis of borderline and assigned to four subgroups. After reviewing the literature and presenting thorough case histories of the 19 patients, the authors consider, in a compact, well-organized chapter, the problem of differential diagnosis, a topic all too rarely explored. Although they consider a case of "narcissistic neurosis," the distinction they draw between borderline patients and patients with narcissistic character disorders is insufficient. Similarly, since the diagnosis of schizo-affective schizophrenia is not discussed in any detail, it is hard to tell how the authors differentiate borderline patients from those with schizo-affective schizophrenia.

The book contains a chapter on the family of the borderline patient in which the authors acknowledge that the small sample size limits the conclusions that can be reached. A chapter on follow-up studies leads to the final chapter, which explores the "stable instability" that the authors believe to be characteristic of these patients.

The Borderline Patient is well written with a refreshing minimum of poorly defined psychiatric and psychoanalytic terms that muddy so much of the literature on this subject. Although one could differ with the particular subgroup which the authors assign some of the patients described, the overall effect of their work is to clarify the clinical manifestations of this confused and confusing syndrome.

Striking in this research is the low incidence of the borderline syndrome: only 14 of 300 consecutively hospitalized patients received this diagnosis. However, both this book and *The Borderline Syndrome* consider only hospitalized patients, thus preselecting those with more severe ego deficiencies; the incidence of the borderline syndrome in nonhospitalized patients may be much greater. The psychodynamic formulations offered with each case description are brief, rather superficial, and sometimes not well substantiated by the material presented.

My major serious reservation about this book grows out of the author's therapeutic nihilism regarding psychotherapy with borderline patients, a position apparently reached as a result of their follow-up studies. Without elaborating the kind of psychotherapy their patients received or presenting data to justify their conclusion, they take the position that borderline patients "require direction, control, and education rather than insight, since they do not have the capacity to develop a transference neurosis suitable for psychoanalytic interpretations" (p. 215). Even if one believes that borderline patients do not develop a transference neurosis characteristic of classical psychoanalysis, they do develop powerful transferences, and, as many writers have convincingly demonstrated, they are certainly able to utilize psychoanalytic interpretations. The authors' dismissal of the usefulness of insight-oriented psychotherapy with borderline patients is unwarranted.

Grinker and Werble have provided us with a most helpful guide to diagnosing the borderline patient, but they are on shaky ground when they move from this area into consideration of appropriate treatment for these patients.

DAVID I. JOSEPH, M.D.
Washington, D.C.

Child Psychiatry: Treatment and Research, *edited by Mae F. McMillan, M.D., and Sergio Henao, M.D. New York, N.Y., Brunner/Mazel, 1977, 305 pp., $15.00.*

A collection of the writings of several authors is often said to be the easiest book one can produce. However, this book is too good to have been collected and edited without hard work and struggle. Drs. McMillan and Henao have brought into usable and sensible shape a number of symposium presentations that must have had more roughness and more diversity in earlier forms than they have in print.

Editorial rigor has not homogenized the final product, however. The authors' personal styles persist in the 16 chapters of the publication—styles ranging from the restrained tone of Sally Provence to the witty and erudite review by Norman Garmezy to the fragmentary, sophomoric, and unorganized commentary of Michael Baizerman. The good is mixed with the not so good. Some of the styles and sub-

stance of different chapters stand out as essays of extraordinary merit. Worth the cost of the entire book is the brilliant, tightly reasoned, and judicious article by Saul Harrison titled "Reassessment of Eclecticism in Child Psychiatric Treatment." That chapter is praiseworthy through and through. For other chapters it is only difference from its neighbors that occasionally gives a nearly drab chapter some spiciness, imparting a welcome change of pace, as seen, for example, in the chapters by Lee Robins and Eric Wish, Judith Wallerstein, Sally Provence, and Ronald Liebman and associates.

Not even the lingo of public health bureaucracies subdues the sprightliness and human glow of Margaret Morgan Lawrence's chapter on inner city families. An example of the lingo is her question, "What are the effects of deficits existing in mother, infant, family, and community, including deficits in nurturing over several generations, on infant-caretaker interaction?" (p. 79). "Infant-caretaker" must mean mother-child. Not even the pose of bantam rooster daring and dogmatism can salvage much of the chapter on asthmatic children by Ronald Liebman and associates from the Philadelphia Child Guidance Clinic, however. More than assertive oversimplification is required to sell their patriarchal product: "It changes the role of the father in the family by increasing his involvement in a constructive manner." Again, intricate statistical ploys, caveats, and jugglings cannot breathe life into the chapter by Robins and Wish, who studied a group of 223 black men in their developing "deviances." From page 254 we learn, "Qualitative relationships were tested by an age-adjusted actuarial method followed by tests for spuriousness which required holding constant acts that were presumptive causes of both members of a pair of acts as well as the total number of prior acts."

Peter Wolff, on the other hand, interestingly supports the view that child psychiatrists must look at maturation apart from chronological age. Wolff presents material on CNS maturation and behavioral development that, although not startlingly novel, is provocative of thought and consistent with reason:

> The left cerebral hemisphere has been characterized as processing by focal, analytic, or serial strategies, and the right hemisphere as extracting information by the diffuse, holistic, gestalt mode or by strategies of "parallel" processing. . . . Such characterizations are only a rough approximation of actual conditions, but they have the heuristic advantage of grouping a large number of heterogeneous psychological tasks under a few formal rules, and of directing research efforts to a functional analysis of brain mechanisms.

The chapter by Milton Shore is lightly informal but does provide some sustenance. One is assured that Shore has indeed been taught a lot by delinquent adolescents; would that the same were true of other writers on adolescents in this volume.

Several typographical errors mar this otherwise attractive piece of work. Page 263 stirs our curiosity with an obvious misprint—"female-to-female transsexuals." Page 144 would lead us to believe that Dr. Stickney was succeeded as Commissioner of Mental Health and plaintiff in a class action suit in Alabama by an unknown, unheralded figure: "*Wyatt v. Anderholt.*"

Overall, this is a worthwhile, far-ranging, and representative compendium of the field of child psychiatry. It will not be timeless, but we can derive reassurance that as rapidly as it has been superseded the scientific footing of child psychiatry will have been strengthened. Its sampling is a good one for now.

PAUL L. ADAMS, M.D.
Louisville, Ky.

Endangered Hope: Experiences in Psychiatric Aftercare Facilities, *by David K. Reynolds and Norman L. Farberow. Berkeley, Calif., University of California Press, 1977, 180 pp., $10.95.*

In the introduction to this short informative study the authors state their intention to explore, using an experiential research design, the impact of placement of suicidal patients recently treated in an inpatient psychiatric facility into residential aftercare facilities.

One of the authors (David Reynolds), with a case history based on his own life history, entered a number of aftercare facilities as a "discharged patient" to make firsthand observations of the facilities and gather data about his own reactions and the reactions of the owners and residents to him. His experiences and the brief experience of one other researcher are the major focus of the book. From these experiences, the authors have formulated conclusions and recommendations regarding this phase of treatment for the suicidal patient.

Despite the authors' intention, the study offers relatively little insight into the specific consequences of placement in an aftercare facility on depressed and suicidal patients. Rather, the book's primary value is in highlighting clearly the impact of these settings on all mentally ill persons and in offering constructive recommendations to those involved in these settings as to how they can have a more positive effect on the clients. This volume is particularly timely because of the current concerns about the process of deinstitutionalization and the need for developing appropriate and effective residential settings in the community that can serve as transitions from the hospital to independent living.

The authors delineate four stages that characterize the process encountered by the discharged patient who enters a residential aftercare setting. Although only briefly described, the stages of newcomer status, interim phase, membership phase, and termination phase are valuable concepts that can be used by other researchers in further describing this process.

There are other important subjects that the authors touch on. In some instances they make important contributions to our knowledge. These include a description of the role of owner-managers that highlights the need for the development of adequate training programs for them, 2) the second-class status often felt by residents, in comparison with staff, and the kinds of staff actions that can decrease the stigma of placement in a residential facility, and 3) the conclusion that an effective network of residential facilities must include a variety of settings in which programs are specifically targeted for different types of patient problems and for different levels of independence.

Despite this book's many substantive contributions to our knowledge about placement and care in residential aftercare facilities, there are some shortcomings that call for further research and exposition. In only one of the settings was the research conducted over a fairly lengthy period of time (four weeks). In all other settings, the researcher remained for a much briefer period of time. Furthermore, the two researchers spent time together only in one setting, thereby limiting

the opportunity for consensual validation of their observations, an important methodological consideration. Further research of this nature should allow for a longer period of placement of the observer-researcher in such a setting to more accurately delineate the four stages conceptualized by these authors.

The authors pay insufficient attention to the perceptions of the residents about their own reactions to the pseudo-patient. In emphasizing the reactions of the owners, I think the authors have overlooked an equally important area for study.

In summary, *Endangered Hope* is a valuable addition to our limited existing literature on the experiences of mentally ill individuals who require placement in a residential aftercare setting as part of their treatment plan. In the light of our increasing awareness of the need to focus greater attention on the problems faced by those with chronic mental disabilities, it is my hope that further research in this area will take place.

ALLAN BEIGEL, M.D.
Tucson, Ariz.

Psychotherapy for Better or Worse: The Problem of Negative Effects, *by Hans H. Strupp, Suzanne W. Hadley, and Beverly Gomes-Schwartz. New York, N.Y., Jason Aronson, 1977, 343 pp., no price listed.*

This volume is devoted to the question of whether psychotherapy can have harmful effects or increase a patient's suffering. Those familiar with Dr. Strupp's previous work will not be in the least surprised to find a highly readable, well-researched, and well-referenced discussion of this issue. They will also find that Dr. Strupp and his colleagues have thought of and discussed almost every question that this issue might bring to mind.

The book consists essentially of two parts, the first of which could be called "Dr. Strupp and His Colleagues" and the second, "The Respondents." There are three main sections to the first part: a presentation of the problem of negative effects with a discussion of the relevant literature, a detailed analysis of previous psychotherapy studies relating to claims of harmful or negative effects, and the proposal of a model for evaluating the mental health and psychotherapy experience of a patient.

This model, called the "tripartite model" by Strupp, is based on the fact that three major parties are concerned with a patient: society (including significant people in the patient's life), the individual patient, and the mental health professional. From these three he obtains three readings of the state of a patient, and these three readings make up what he calls the BWS configuration: B is society's perspective, concerned principally with the adaptive qualities of the behavior of the patient; W is the individual's own sense of well-being; and S is the evaluation of the mental health professional, who bases judgment on an assessment of psychological structure. Strupp says that these dimensions should be considered simultaneously in evaluating mental health and changes related to psychotherapy.

The authors make clear in their analysis of previous studies that almost every study has had some serious flaws, and the only study that they feel fulfills certain criteria in terms of selection, methodology, design, etc., found a very low rate of negative effects.

The second part of the book is in some ways even more enjoyable and stimulating than the first. It consists of the replies of a number of well-known people in the fields of psychiatry and psychology to a letter sent to them by Dr. Strupp. In his brief letter he asked them to respond to three questions that can be summarized as follows: 1) Is there a problem of negative effects in psychotherapy? 2) If so, what would constitute a negative effect? 3) Which factors do you consider mainly responsible for a negative effect?

The replies of 70 respondents are printed here, and there is a chapter discussing the "expert's opinions." The replies vary in length from five lines to Paul Meehl's 16 pages, and they are all well worth reading.

Certain points emerge repeatedly, to the extent that I think it is fair to speak of a consensus among psychotherapists. Abram Kardiner wrote in *My Analysis with Freud* (1), "Freud was always infuriated whenever I would say to him that you could not do harm with psychoanalysis. He said, 'When you say that, you also say that it cannot do any good. Because if you cannot do any harm, how can you do good?' " This opinion seems to be shared by most of the respondents, and other areas of agreement also seem to be present.

Exacerbation of symptoms, hospitalization, overt psychosis, suicide, long-term lowered self-esteem, loss of trust in the therapist or in therapy, and excessive dependency on the therapist are considered negative effects by psychotherapists.

There also seems to be fairly wide agreement about a number of factors that can lead to negative effects. Prominent among these are inadequate assessment of the patient, unsuitability of the patient for psychotherapy, poor motivation on the part of the patient, pathology of the therapist (especially hostility and seductiveness), the therapist promising more than he or she can deliver to the patient, and conveying lack of respect and lack of hope to the patient. For the most part, the onus is very much on the therapist, which emphasizes the great difference in outlook between psychotherapists and organically oriented psychiatrists.

Of course, some of the respondents took the opportunity to express their hostilities toward people or approaches they disapproved of, and a considerable number (16 out of 70) advertised their own book or paper, but as a whole the responses make very interesting reading and give us a good representative picture of therapists' thoughts and experiences in this area.

Two replies are especially noteworthy: Goldberg's (page 263), characterized by its clear conceptualization and excellent synthesis of what constitutes negative effects and why they occur, and the lengthy response of Meehl on page 306.

Some experienced therapists may read this book and feel that the authors have not told them anything new. There is a well-known Talmudic saying: "Know how to answer one who comes to ridicule or attack you," and the authors make it clear that one of the main reasons that this book was written was because "contemporary society [has a] critical view of psychotherapy," and "legislators, insurance companies . . . consumers . . . have begun to demand from the mental health professions clear-cut answers to the extraordinarily difficult and complex questions concerning what psychotherapy does and how it does it."

The thoughtful and concerned psychotherapist will benefit greatly by reading this well-written and nicely produced book. It will give the psychotherapist a much fuller understanding of these issues and a feeling of support from a con-

siderable number of outstanding contributors in the field of psychotherapy. It is more permanent, more enjoyable, and much cheaper than a three-day symposium on the topic.

Downsview, Ont., Canada

Suicide: Inside and Out, *by David K. Reynolds and Norman L. Farberow. Berkeley, Calif., University of California Press, 1978, 237 pp., $3.85 (paper).*

This volume details the experience of a pseudo-patient (David Reynolds) who was admitted to a Veterans Hospital for a two-week stay. The presenting complaints are carefully prepared, the case history is well documented, and the pseudo-patient's subjective responses are nicely recorded. The suicidal story is central to the authors' thesis. The authors recognize the highly subjective nature of the experience and make serious attempts to understand patienthood within a special framework.

The book is useful reading from a number of standpoints. It offers, first, a good review of the pseudo-patient in a psychiatric hospital. It presents data on suicide in the psychiatric setting and tries to correlate the frequency of suicide with the absence of humanized behavior and the loss of self-esteem. It does not sufficiently separate suicidal thoughts from suicidal acts.

It is not easy for staff to deal with successful suicide in a psychiatric hospital. A suicide will cause a great deal of soul searching, and a psychological autopsy is a common sequel. The affect and emotional investment of staff are not dissimilar in spirit to the agitation of the surgeon when a patient dies on the operating table. The calculated risks taken in serious circumstances are forgotten in the face of the dramatic turn of events.

The authors recognize how, under the best of conditions and with close observation, many opportunities for suicide exist in psychiatric hospitals. It is impressive how few successful attempts occur in large psychiatric hospitals, where less than ideal conditions may exist. In the hospital where I work, more than 5,000 adults are admitted to the inpatient service per year. Over the years these patients have been increasingly more agitated, with a substantial proportion verbalizing suicidal ideation. Still, a check of the records shows only one successful suicide in the past 5 years. (An additional suicide in that period occurred on the prison service, a circumstance that deserves a review all by itself.)

I point this out to indicate that the book would have been just as valuable to me if the thrust had been away from suicide to a reexamination of the social structure within the hospital and its impact on patients. Humanizing the hospital setting is important not only for patients but for staff. Patients will respond with a greater sense of responsibility, and the hospital community will be more happily structured.

The diary of the patient is well worth reading. It is important to bear in mind that the sense of patienthood in the pseudo-patient is highly variable and that not all observers may slip so easily into the patient role. All in all, I found the book readable and its thesis "good." Others who read this may wish to speculate about other factors that may lead to suicide in the psychiatric hospital.

MARVIN STERN, M.D.
New York, N.Y.

Psychiatrists and the Legal Process: Diagnosis and Debate, *edited by Richard J. Bonnie, LL.B. New York, N.Y., Psychiatric Annals (Insight Communications), 1977, 345 pp., $5.00 (paper).*

The editors of *Psychiatric Annals* apparently discovered one day that in the brief course of that publication's existence a number of very interesting and some distinguished articles on legal psychiatry had been published. They decided that collecting these articles in a volume would be an addition to the legal psychiatric literature, which was almost nonexistent 20 years ago but is now expanding at a rapid rate.

As Richard Bonnie says in his introduction to this collection of 43 articles, "The mushrooming interest in cross-disciplinary work is reflected . . . in the number of treatises and texts that have been published in recent years." This volume is an addition to this burgeoning literature. The authors included represent a *Who's Who* of current legal psychiatry—among them William J. Curran (more identified with legal medicine but contributing an interesting historical paper on legal psychiatry), Seymour Pollack, Carl Malmquist, Abraham Halpern, Seymour Halleck, Donald Hayes Russell, Darold Treffert, Browning Hoffman, Stonewall Stickney, Alan Stone, and Loren Roth.

Like any collection of articles that have appeared in a periodical, the quality varies widely, but some of the articles are extremely important. Among my favorites is "The Chronically Mentally Ill Shuffle to Oblivion" by Robert Reich and Lloyd Siegel, which in 1973 called attention to the neglect of many of those caught up in the process of deinstitutionalization. Darold Treffert's consideration of "The Practical Limits of Patients' Rights" and Browning Hoffman's response to that position represent a dialogue that is worthy of a great deal of consideration, and Stonewall Stickney's retelling of his position in *Wyatt v. Stickney* is an important explication on the background of one of the major forensic psychiatric cases. Many other articles in this collection are equally worth reading and worth having in a convenient reference source.

Richard Bonnie, who is Professor of Law at the University of Virginia School of Law, has divided the articles into four categories: Roles of Psychiatrists in the Legal Process, Psychiatrists and the Criminal Process, Psychiatrists and the Juvenile Process, and Psychiatrists and the Mental Health Process. He has written very useful introductions, summaries, and commentaries for the articles in each section.

It would be difficult to read this collection from start to finish. It contains too many ideas, some of the points of view of the various authors are contradictory rather than complementary, and, in spite of the great efforts of the editor to give continuity and unity to the work, it lacks the bite and the interest of a work by one author. However, if it cannot be read comfortably from start to finish, many sections are extremely readable, and it certainly belongs in the expanding reference shelf of important legal psychiatric works.

One extended section of the book is a consideration of the insanity defense of Loftus E. Becker, Jr., Associate Professor of Law at the University of Minnesota; this represents

five articles that appeared in two issues of the magazine and is really a monograph on the subject. Three articles by Donald Hayes Russell (all from one issue of the magazine) similarly comprise a monograph on juvenile delinquency.

Much in this volume, like much in forensic psychiatry, is controversial. Such topics as the right to refuse treatment or the proper use of the concept of rehabilitation in criminal justice will continue to be debatable.

The title of this book is somewhat unwieldy. On the cover and on the title page the first part of the title, "Psychiatrists and the Legal Process," is put in smaller type than the rest of the title, "Diagnosis and Debate." Whichever of these titles is used, this compilation represents an impressive collection of authors and contributions and a remarkable illustration of the great attention that is being paid to a variety of legal psychiatric topics.

JONAS ROBITSCHER, J.D., M.D.
Atlanta, Ga.

Psychological Medicine: An Introduction to Psychiatry, 8th ed., *by Desmond Curran, M.D., D.P.M., Maurice Partridge, D.M., D.P.M., and Peter Storey, M.D., D.P.M. New York, N.Y., Churchill Livingstone, 1976, 434 pp., $14.50 (paper).*

This is a straightforward and, in my view, somewhat simplistic textbook written expressly for medical students. One has to take into account that this is an English textbook written for English medical students, who are warned against foreign influences. For instance, when writing about schizophrenia, the authors write, "It is important to realize that many psychiatrists abroad, particularly in the U.S.A. and U.S.S.R., would not share the views put forward here, and this should be remembered when reading foreign articles or books."

Psychotherapy is given short shrift and is deemed to be contraindicated in the treatment of schizophrenia, the author's opinion being that it "unfortunately tends to make schizophrenic patients worse." There is a curious chapter titled "Peripheral Psychiatry" that covers psychosomatic medicine, anorexia nervosa, nocturnal enuresis, stammering, sleepwalking, tics, spasmodic torticollis, acute intermittent porphyria, and electroencephalography, all in strange juxtaposition and contained in 12½ pages.

Although it becomes obvious that it is unlikely that this textbook will be used by American medical students, it has been reprinted 11 times and is in its 8th edition. Its description of group therapy is almost worth the price of the book: "Free discussion and straight forward self-disclosure is encouraged among not more than eight patients at a time—the ideal number, as Lord Houghton declared, for 'a polite dinner party,' though, especially as inter-relationship develops, the groups are not always 'polite.' "

Thought, Consciousness, and Reality: Psychiatry and the Humanities, Vol. 2, *edited by Joseph H. Smith, M.D. New Haven, Conn., Yale University Press, 1977, 309 pp., $15.00.*

This collection of essays by five philosophers and four psychoanalysts achieves greater thematic unity than did volume 1 (1). It presents relevant reflections on thought, consciousness, and reality in two groups of essays: five papers under the general heading of Thought and Consciousness and four papers under the title The Construction of the Real.

The nature of thought and its relationship to reality appeared as problems very early in the history of Western philosophical inquiry. They received classic consideration in Plato's "Thaetetus," in which he advanced the idea that thinking is merely silently talking to oneself. The question continued to figure prominently in philosophical discourse throughout the centuries as part of epistemological considerations.

Freud became involved with the problem early in his work. Although his classic paper "Formulations on Two Principles of Mental Functioning" (2) was not published until 1911, he had been occupied much earlier with the nature of man's mental attitude toward reality. A high point in psychoanalytic concern with the character of thought was reached by David Rapaport in his *Organization and Pathology of Thought* (3).

This collection of essays largely takes its theme from the first and keynote essay by Stuart Hampshire, an English philosopher, titled "The Explanation of Thought." The paper constitutes a rethinking of Spinoza's double aspect theory in its relation to the nature of thought. Spinoza was concerned with the ability of reason to influence our actions and with the essence of human freedom. Parenthetically, the latter problem is discussed at length later in this volume in a critical essay by Isaac Frank titled "Spinoza, Freud, and Hampshire on Psychic Freedom."

Hampshire's argument begins with calling attention to the reflective nature of states of mind as a good basis for denying the unrestricted and strict application of deterministic conceptions to mental events. He advances the hypothesis that the explanation of thought will always require links under the laws of thought, which are unlike physical laws in that the former are normative in part. The correlation between a physical input—a chemical in the brain, for instance—and the observable outcome "is of a different kind from the causal connections between behavior and the beliefs, desires, and other propositional attitudes that are involved in man's thinking."

In the second essay, "Words in Thoughts," Zeno Vendler, a professor of philosophy, argues that the Platonic view that thinking is talking to oneself silently is implausible and false. He demonstrates his point of view with subtle analysis and use of syllogisms. For example: "To sum up: talking, saying things, are voluntary actions. Having certain common types of thoughts cannot be voluntary, consequently, thinking in general cannot be talking to oneself, silently or aloud. . . . Language is the means of expressing thoughts, not of having them."

The next essay, "Dreams, Memory, and the Origin of Thoughts," is a very provocative contribution by Stanley R. Palombo, an American psychoanalyst. It is based on information theory and offers an intriguing phylogenetic hypothesis that the "mechanism of dream construction may have been the first step in the evolution of reflective consciousness." Palombo considers conscious, reflective, secondary process thought to be "the apex of a vast pyramid of adaptive mental activity."

Albert Hofstadter, a prominent American philosopher, contributes an elaborate and interesting application of the concept of alienation in his paper, "Consciousness, Thought, and Enownment." Enownment is, in Hofstadter's terminology, the appropriation of "otherness." However,

he says, "Thinking is not the only mode of appropriating otherness. Practice is more fundamental."

The first section of the book concludes with "Analytic Philosophy, Phenomenology, and the Concept of Consciousness," by Harold A. Durfee, an American philosopher. This highly philosophical paper deals with the schism between analytic (classical) philosophy and phenomenology and its reflected analogous conflict in psychological theory. Durfee concludes that "diverse interpretations of the nature of consciousness lie at the heart of this controversy." This discussion is difficult to follow for those unacquainted with these philosophical currents and the specialized vocabulary.

The second part of the book consists of four essays covering a diversity of subjects related to the central theme. John S. Kafka's paper, "Object Constancy, Ambiguity, Paradox, and Time," focuses on ambiguity and temporality. Kafka uses Russell's theory of types in an attempt to understand ambiguity and levels of psychoanalytic explanation. W.W. Meissner's essay delves into the theory of the process of paranoia and analyzes the importance to psychiatry of the distinction between fantasy and reality. In Wolfgang Loch's essay on the concept of truth in analytic theory, scientific and existential truths are distinguished and the consideration of the problem of meaning by Gottlob Frege is introduced.

The profundity of much of the material covered in these essays is truly challenging and intriguing. The collection is hardly for late-night reading, but it is a truly rewarding intellectual experience. I cannot refrain from quoting part of the last paragraph of the introduction:

> While the mind is the ever-present focus of attention of both fields [philosophy and psychiatry], each also tends to approach the real. These essays constitute an interdisciplinary consideration of these mutual concerns and of the theoretical issues implicit therein. They also exemplify that when psychiatry lives on the borderline of the humanistic disciplines . . . it lives uniquely and authentically on its own most significant frontiers.

I recommend this book wholeheartedly to the serious student of these matters.

Working with Patients: Introductory Guidelines for Psychotherapists, *by Helen A. De Rosis, M.D. New York, N.Y., Agathon Press, 1977, 190 pp., $10.50.*

Doctor De Rosis has presented the novice with a straightforward, direct, no-nonsense approach to psychotherapy. She assumes that the beginner will be dealing with hospitalized patients at a stage of illness where interpretive, reconstructive psychotherapy is not likely to be the treatment of choice. Her emphasis is on the healthy aspects of the total person rather than on pathology, and on the need to learn from the patient rather than to impose a theory of personality development on him or her. The book is a worthwhile primer, although it is likely that those who might benefit the most from reading it will dismiss it as too superficial.

The Heart Patient Recovers: Social and Psychological Factors, *by Sydney H. Crogg, Ph.D., and Sol Levine, Ph.D. New York, N.Y., Human Sciences Press, 1977, 417 pp., $14.95.*

This volume should be of general interest to *Journal* readers and certainly of specific interest to all primary care physicians, members of health care teams, health planners, and lay persons who are required to cope with the stresses of heart disease. Indeed, the potential readership encompasses a remarkedly large number of persons. Croog and Levine systematically and empirically studied several hundred previously healthy men during the one-year period following their hospitalization for a first myocardial infarction. Their concern was to observe and record this major life event as a stressor whose sequelae are influenced by many social, psychological, and physical variables. To my knowledge, this is the first such endeavor; therefore, the volume brings a fresh and extensive new data base.

Special chapters are given over to discussions of morbidity, mortality, and rehospitalization; employment and work experience; financial influences; institutions; physician advice and compliance; the patient's family; personality and psychological factors; and a review of variables relevant to the status of the patients at the conclusion of one year of study. The dramatic advances made in the hospital treatment of the acute myocardial infarction, including continuous monitoring in coronary care units by highly skilled health care teams, represent a well-known landmark in medical history. Croog and Levine provide a timely and scholarly work that uncovers and reveals the essentials of a quality recovery period through a comprehensive rehabilitative process. Such an idea would seem humanistically obvious; however, the authors are adept at pointing out both the complexity of the comprehensive recovery process and the deficiencies in future health care planning for addressing this issue.

This is a good book. It is unique because, as a very scholarly work, it should directly influence the behaviors and serve as a reference for a broad spectrum of persons in our society, including professionals, politicians, and, most importantly, the heart patient and his or her family. Behavioral scientists who are able to produce high-quality work of social relevance and pragmatism within the appropriate restraints of scientific methodology are to be congratulated.

And a Time to Live: Toward Emotional Well-Being During the Crisis of Cancer, *by Robert Chernin Cantor. New York, N.Y., Harper & Row, 1978, 276 pp., $9.95.*

Dr. Cantor has written what amounts to a significant book on personality development. Admittedly, its core is the crisis

of cancer. Cancer is a stress; the disease is anxiety provoking and demands coping techniques. Similarly, even if one does not have cancer, one is not spared other sources of anxiety as one goes through life, and thus defense mechanisms and behavior patterns develop experientially. How one deals with living will determine how one will deal with dying.

It is within this framework that Dr. Cantor has provided us with a useful textbook. To his credit, it is without the usual psychological jargon. The format consists of four parts. Part one, The Cancer Experience, explores all the emotional parameters of the patient's experience: the impotent anger, the frightening fantasies, the guilt, the depression, the very crucial fear of loss of control over self and/or therapy. This section overlaps into part two, The Sphere of Personal Influence. Part Three, The Sphere of Family Influence, presents interesting psychological paradigms of marital and familial patterns of relationships. Part Four, The Search for Meaning, offers religious experiences and personal experiences extrapolated philosophically to substantiate faith and constructive justification for the adverse encounter.

It was in part two that I found myself notably involved with the author, and on two counts. On the first point, with concurrence: the right to die. In the depressed (noncancer) patient, suicide is a symptom. In the case of the patient who has suffered long from a life-threatening illness, the final judgment to discontinue further therapy is the patient's and not the professional's or society's.

The other segment in part two evoked uncomfortable feelings. In the section titled "Actively Influencing the Disease Cancer" the author in essence proposes that mentally and emotionally, "fighting back" can inhibit actual tumor growth or physical incapacitation. He cites the usual anecdotal support plus the capacity of biofeedback to affect bodily physiological functions and the visualization techniques developed by the Simontons. The latter approach encourages the patient to relax and to visualize his cancer, the anti-cancer treatment, and his body's immune responses. Generally, the visualization is in graphic imagery.

There is some question as to the validity of anecdotal confirmation (although someone has hinted that anecdotes are scientific facts that have not as yet been published). Furthermore, transient artificial and actual remissions do occur. There is no dispute with the author here; my issue with him is concern for the lay reader. The nonprofessional (and the professional, too, at times) can interpret this material as evidence of personal culpabitity for deterioration of the illness, that he has failed to develop a positive attitude, or that he is a bad patient. The author is not oblivious to this possibility. However, his caveat can be easily overlooked because it consists of one sentence enveloped in the last paragraph of the section: "Continued tumor growth implies no moral or emotional failure" (p. 135).

Despite the mild objection just stated, this book is a useful one. It has a readable style, almost fictional in its many clinical and poignantly dramatic examples. Its lack of sophistication is an asset, and I recommend it for cancer patients and their families. Workers in the area of family and couple therapy might find part three, The Sphere of Family Influence, interesting and educationally worthwhile.

Dr. Cantor's book is in effect a psychiatric text that uses cancer as a vehicle for stress from which to form psychological concepts. Therefore, it is commended to medical, nursing, ministerial, and other associated health care students. They can avail themselves of the opportunity to understand "human nature" and, as a possible bonus, to learn something about the emotional ramifications of the disease of cancer.

Baltimore, Md.

Problem Behavior and Psychosocial Development: A Longitudinal Study of Youth, *by Richard Jessor and Shirley L. Jessor. New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1977, 267 pp., $16.00.*

This research monograph concerns the complex psychosocial variables that influence the adolescent in making the transitions from child to adolescent and from adolescent to young adult. Adolescence is a long period of time that is neither psychologically nor socially homogeneous. Therefore, longitudinal, multifactorial studies like the one reported here are important. This type of research is hard to conduct and difficult to evaluate, as is this study. However, the important trends reported here make this an important research contribution.

The research design involved 400 high school and 200 college youth, male and female, evaluated yearly for four consecutive years by means of a 50-page personal questionnaire. Using parallel samples from the seventh grade through college, the authors provide a picture of the transitions from grade school to high school, high school to college, and college to the adult world.

The authors' social-psychological theory focuses on the role of three component structures of personality: a motivational-instigation structure, a personal belief structure, and a personal control structure. The authors devised a series of measures for each. They then correlated the assessed construct scores with three transition behaviors of adolescents: beginning to drink, starting to use marijuana, and becoming a nonvirgin.

The correlations between scores on the three personality constructs and the three "problem behaviors" are modest but statistically significant. The overall trends of the summary findings have more face validity than the isolated correlations. In brief, problem behaviors tended not to be isolated events but were associated with each other as a syndrome of multiple problematic behaviors. In general, traditional and conventional backgrounds, associates, and attitudes best predicted absence of problematic behavior in adolescence. Adolescents who expressed great concern for personal autonomy, a lack of interest in the conventional goals of church and school, and a jaundiced view of the larger society were most apt to engage in problematic behavior.

These findings may serve as an antidote for those who propose that a laissez-faire approach to self-actualization is the vortex of adolescent development. On the other hand, the authors' personality constructs are very broad and imprecise but their problem behaviors are very specific, so only the most modest of generalizations can be made. More precise personality constructs might have been achieved through the use of more apt measures for each construct. For example, the religious measure uses a very simple liberal-conservative continuum to assess the importance of church membership. The liberal-conservative concept has a low correlation with behavior, as does chruch membership per se. Here the authors could have sharpened their approach through several sophisticated psychometric scales of religiousness that have high correlations with behavior. They ignored such sophisticated measures and instead used their own idiosyncratic

scale. Similar limitations are found in other scaling measures.

Despite my caveats about design, concepts, and assumptions in this study, it stands as an exceptionally well-executed and carefully analyzed piece of research. As a longitudinal study of adolescence it is highly valuable. The working clinician may well find the intricate detail tedious, but the serious scholar will have to take this work into account.

E. MANSELL PATTISON, M.D.
Irvine, Calif.

Observing Behavior, Vol. 1: Theory and Applications in Mental Retardation, *edited by Gene P. Sackett, Ph.D. Baltimore, Md., University Park Press, 1978, 409 pp., $24.50.*

Observing Behavior, Vol. 2: Data Collection and Analysis Methods, *edited by Gene P. Sackett, Ph.D. Baltimore, Md., University Park Press, 1978, 108 pp., $12.50.*

These two volumes comprise the proceedings of a conference on observational/ethological methods in the study of mental retardation held at Lake Wilderness, Wash., in June 1976. The week-long conference involved the intensive interaction of the 41 contributors to these volumes, most of whom are psychologists and specialists in mental retardation. The work has been edited more successfully than most conference reports into clearly organized volumes. However, it remains a publication of congress proceedings with varied material and different degrees of sophistication about other work done in psychology, anthropology, sociology, child psychiatry, and sociobiology relating to observations of the mentally retarded.

The authors accept the general premise that observational methods can be quantified, and that observations can be examined ethologically and ecologically for the purpose of improving the care of the mentally retarded. They begin with the premise that ecology can be acceptably defined as the "complete study of behavior as it occurs in the natural habitat." Some presentations are adduced to prove that this perspective is novel and helpful in approaching retardation. The authors report on parent-infant interaction, cognitive development, language development, group process, and community process.

A particularly intriguing section by Edgerton and Langness describes retarded individuals in a community setting, and there are intriguing clusters of information about studies in language development. However, the overall problem with the first volume is that much of the work represents the beginning development of the view the authors term "ethologic." They provide no convincing synthesis that ethology goes beyond good conventional approaches to language, cognitive development, or mother-child interaction. Trendy phrases, such as "social ethology, ethnology, and ethological psychology," are evident, but the investigations of naturalistic observation versus experimental approaches appear to restate the long-standing, long-unreconciled problems faced by the behavioral sciences.

Volume 2 is more sharply focused on problems in the scientific classification of behavioral observation, its analysis, and its measurement and relates quite specifically to people working on these problems. There are some intriguing data for psychiatrists in the sections on cognitive and language development, but these two volumes are primarily resource documents for investigators in this perspective on human behavior.

NORMAN R. BERNSTEIN, M.D.
Chicago, Ill.

Social Development in Childhood: Day-Care Programs and Research, *edited by Roger A. Webb. Baltimore, Md., Johns Hopkins University Press, 1977, 192 pp., $12.50; $3.45 (paper).*

As the title suggests, this book is primarily concerned with the social development of children in day-care centers. In his introduction the editor indicates that the six chapters in the book report different research projects on infants and latency-age children. The papers were presented at a Hyman Blumberg symposium on research in early childhood education. Earlier volumes in the Blumberg symposia series dealt generally with the intellectual development of young children. The present research deals with problems in social development, particularly as it is observed in various group care situations. The nine contributors are psychologists who have been involved in research on early childhood development in various sections of the United States.

In chapter one, "Mother-Child Interaction in Day-Care and Home-Reared Children," Mary Blehar reports on her own and other research dealing with the effects of daily substitute care. She reports on what she calls the "strange situation: a method for assessing quality of attachment." This "strange situation" was originally developed in the course of a longitudinal study on the development of infant-mother attachment in the first years of life. In the study, children were observed in their reactions to their mother and then in their responses when a stranger was introduced into the room and the mother left the room. Similar patterns of attachment behavior and changes in these patterns were observed with children up to the age of four. This research work is very important because of the increasing number of women who are working outside the home and who are either placing their children in day-care centers or introducing strangers into the home to take care of their children. Comparisons have also been made between children who remain at home with their own mothers and those who have nonparent figures in the home.

In chapter two Mary Main makes an analysis of a peculiar form of reunion behavior seen in some day-care children. It has been observed that some one-year-olds avoid their mothers after a brief separation in a strange environment. In the "strange situation," the child avoids his or her mother after a brief separation. This avoidance has been shown to be related to angry behavior, to a set of odd behaviors, and to an unwillingness to interact with persons other than the mother. Main quotes Blehar in this volume to indicate that avoidance of the mother in the "strange situation" appears more strongly in day-care children than in home-reared children.

In chapter three, Ramey and Mills discuss the social and intellectual consequences of day care in high-risk infants. The infants in this particular research program ranged in age from three and a half months to nine and a half months. This research indicated that children who were enrolled in a special project scored significantly higher on the Bayley Scales of Infant Development than matched control individuals reared at home. The authors also report that high-risk infants in day-care centers had a social relationship with their

mother similar to that of general population infants. The authors emphasize that day-care programs vary and that additional studies are needed to determine whether or not other day-care programs encourage the infant in his or her social relationship with the mother.

In chapter four Webb, Oliveri, and Harnick write about the socialization of intelligence. They reviewed three studies and indicate that two different approaches to the problems of social influence on intellectual style have been attempted. The research was done in a series of nursery schools in Baltimore City. Children were assigned on a random basis to experimental and control groups. Teachers in the control schools received no special instructions. The experimental teachers were provided with a series of nine lesson plans that were distributed and discussed biweekly at teachers' meetings. The lesson plan had two levels of content. One level was specific to individual lessons, and the second was a study of the teacher-child interaction. The authors report that six months of intensive intervening produced highly significant differences according to the Bayley scales.

Greif, in chapter five, reports on peer interactions in preschool children and emphasizes that preschool children can learn from their own peers as well as from older children and adults. Children exchange information about the world and themselves.

In chapter six Elardo reports on "Project Aware." This program deals with latency-age children. In group meetings the leader tells the children a story and then the children participate in discussions about it. In addition, special guidance is given to teachers.

Some portions of this book are repetitive, particularly those dealing with the "strange situation." The emphasis in all of these chapters is on social rather than intellectual progress in children who were seen either in nurseries or day-care centers. The work is of particular interest to psychologists and child psychiatrists who are concerned about the early development of the child and who are now especially concerned because of the increasing number of mothers who go to work. I recommend this small volume to all those involved in the care and education of infants and small children.

FRANK J. CURRAN, M.D.
New York, N.Y.

The Dynamics of University Protest, *by Donald Light, Jr., and John Spiegel, with C. J. Lammers, R. S. Laufer, M. Levin, and J. L. Norr. Chicago, Ill., Nelson-Hall, 1977, 198 pp., $12.00.*

This book examines such topics as the origin and future of university protest and the literature on student unrest. It also examines the context in which protest occurs: the tactics of students, the responses of faculties, the psychology of the disorders themselves, and the tactics and strategies adopted by administrators to counter student opposition.

The Dynamics of University Protest makes a significant contribution to the literature by bringing together analyses of what were commonalities of response by different groups on campuses across the United States. Most previous books on the subject have described in great detail what occurred at such campuses as Berkeley, Harvard, Columbia, Kent State, and Jackson State.

Several chapters merit special consideration. Chapter two, "Point and Counterpoint in the Literature on Student Unrest" by Molly Levin and John Spiegel, provides a thoughtful synthesis of three stages the research literature went through in attempting to increase understanding of student unrest phenomena. The first stage was the analysis of the personalities and backgrounds of dissenters (pathology-in-students versus pathology-in-society); the second was a search for causes and issues (what students were really protesting about); the third was developing methods of coping with legitimate dissent (issues of process and response).

Chapter seven, "Tactics and Strategies Adopted by University Authorities to Counter Student Opposition," is written by a sociologist, C.J. Lammers. He identifies four basic tactics: "fight off," in which there is a maintenance of the difference in power and student leaders are perceived as subversive ring-leaders; "bug off," in which authorities give up a portion of their power and student leaders are spokesmen; "join in," in which some power is shared and the student leadership are innovators; and "stand off," in which power differences remain and student leaders are perceived as ring-leaders and idealists.

What this book does it does well. The analyses of tactics and strategies could well reflect the curriculum of a college of war. However, the topic, dynamics of protest, might have treated two topics in greater detail. First, what ought to be the interrelationship between the different segments on issues of conflict resolution? In other words, given the central university purposes of research, teaching, and public service, what should the structure of governance be to minimize disruptive distraction from pressing issues while at the same time providing for the constructive resolution of strongly felt differences of opinion? Second, the book could have considered the effects of changes of governance structure within universities since the 1960s that have proved to be viable, particularly when juxtaposed to changes that have not been successful. Both society and the university have changed in important ways in the past decade. These changes fundamentally affect the dynamics of protest, as the debate over investments in South Africa indicates, but they do not receive sufficient coverage.

JOHN M. WHITTLEY, ED. D.
Irvine, Calif.

Ethology: The Biological Study of Animal Behavior, *by Rémy Chauvin; translated by Joyce Diamanti. New York, N.Y., International Universities Press, 1977, 241 pp., $12.50.*

This book condenses a considerable amount of material into 241 pages. Separate books could be written and, in some cases, have been written on many of the individual topics covered. A sampling of areas included in this book follows: 1) building behavior of caddis fly larvae, bees, ants, wasps, and birds; 2) animal learning studies; 3) factors affecting migration of animals; 4) sexual attraction and mating behavior in animals and man; 5) the development of affectional systems; 6) imprinting; 7) social organization of chimpanzees, macaques, gibbons, and howler monkeys; 8) animal communication; and 9) definition of major ethological concepts.

As is necessarily the case with books covering so many topics, *Ethology* could be critiqued as being too superficial. However, the author does an excellent job of telescoping key concepts and issues into a relatively short and readable book. Psychiatrists will find a great deal of helpful information concerning ethology. One of the particularly good fea-

tures of the book is its discussion of both field study data and laboratory data in relation to each other. This is rarely done because ethologists and comparative psychologists often unnecessarily denigrate each other's work.

In contrast to many ethology books, this one does not dwell on the detailed analysis of elementary movements and displacements. This type of analysis of behavior into its submicroscopic component parts has been necessary—perhaps even helpful. However, there is an inherent reductionistic error when such dissection techniques are applied to human behavior. The human organism is obviously more than the sum of its component parts. The author's analogy is to a computer in which the innate program is the expression of the nervous system and anatomy but is alterable by instructions to change programs. There is an interaction between the program and the environment, and this is what should be measured and studied. This model is applied to the solitary animal, the family, and social relations.

In view of the increasing importance of ethology in psychiatry, psychiatrists will find chapter nine a particularly helpful reference because it contains a glossary of key ethological concepts. Although some may find it overly terse and overly simplified, I found it helpful.

This is a book to be scanned, not an in-depth explanation of one ethological topic area. Given this framework, it is a useful book that contains literature references for more extensive reading.

WILLIAM T. MCKINNEY, M.D.
Madison, Wis.

Modern Psychoanalytic Concepts in a General Psychology. Part One: General Concepts and Principles; Part Two: Motivation, Psychological Issues Monograph 42/43. *by Allan D. Rosenblatt and James T. Thickstun. New York, N.Y., International Universities Press, 1978, 338 pp., $15.00 (paper).*

The authors of this text of current psycholanalytic theory as it relates to a general psychology of human behavior are to be congratulated. They have produced a very satisfying survey of existing psychoanalytic theory. The volume is succinct, well written, effectively organized, and thoroughly documented. The bibliography is excellent, and the index is very easy to use.

Drs. Rosenblatt and Thickstun do not believe that psychoanalysis is or has the potential for becoming a general psychology in itself. Psychoanalysis as such cannot encompass all human behavior or provide a complete explanation of such fields as learning, memory, or perception. However, psychoanalysis makes its unique contribution to a general theory of human behavior, and this monograph outlines what the authors consider to be the most relevant contributions of psychoanalysis.

Part One is devoted to general concepts and principles. General problems of methodology, systematization, scientific explanation, theories, models, validation, and prediction are discussed clearly and yet not in such detail as to distract from the major emphasis of this work. Brief discussions of modern psychoanalytic core propositions, information processing systems in psychoanalytic theory, and such key concepts as psychic determinism, unconscious mental processes, conflict, anxiety, and the metapsychological points of view complete this first section.

In the second part the focus is on motivation. Such issues as instinct and drive, incentive, and cognitive theories are discussed with an eye toward the presentation of the authors' model of the motivational system. In their last chapter they use clinical data to illustrate their formulations.

I found this work very useful, stimulating, and need-fulfilling. We now have an up-to-date work that can be used by students, researchers, teachers, and clinicians. The two parts of this volume are the first of a projected eight-part work. I look forward to the publication of the remaining six sections. If they are as well done as the first two, the authors have done us a great service.

GEORGE H. POLLOCK, M.D., PH.D.
Chicago, Ill.

Behavioral Approaches to Weight Control, *by Edward E. Abramson. New York, N.Y., Springer Publishing Co., 1978, 175 pp., $12.95.*

This short book consists of nine chapters and nine appendixes; three of the chapters are written by the editor. In the preface Abramson states, "This book will provide the necessary information and materials so that the professional without extensive training in behavior modification will be able to choose and implement a behavioral treatment program" (p. x).

Although I would agree that the editor has generally succeeded in attaining his stated objective, the quality of the different contributions varies. Perhaps the most serious problem is that, with the exception of Abramson's three chapters, the material has previously been published in other sources in 1971–1975. For example, Cautela's description of treatment by means of covert conditioning (initially published in 1972), according to Abramson's own analysis of the research data in chapter two, certainly does not appear to be the behavioral treatment of choice. Similarly, some of the other strategies described in the book (e.g., Fowler's "mouthful diet") have not enjoyed substantial empirical support.

In chapter one Abramson presents a very readable and sufficiently comprehensive overview of the etiology of weight gain and some of the traditional remediation methods that have been employed. However, the statement on page 6 about the impossibility of using humans for experimental studies of genetics is too obvious to be included, even for the lay reader. In chapter two, Abramson gives the reader a brief but inclusive view of the behavioral approach to treatment. Christensen, Jeffrey, and Pappas discuss an operant approach to treatment in chapter three, and Wollersheim outlines a number of the treatment strategies she has used with overweight female college students in chapter four. Although the techniques depicted make good theoretical sense, I question the ultimate wisdom of substituting smoking for eating food during the difficult periods in treatment when cravings are likely to occur. The substitution of one potentially addictive behavior (probably more dangerous to overall health than being overweight) for another has no justification. In chapter five Fowler describes his "mouthful diet" (i.e., decreasing the average number of bites of food per day during treatment), and in chapter six Cautela discusses covert conditioning therapy. In chapter seven Lutzker and Lutzker clearly articulate an interesting contingency contracting approach to losing weight. The contract is to be negotiated between two people (e.g., husband and wife).

The importance of exercise in the initial weight loss effort and in maintaining weight loss is indicated in an extremely

short offering in chapter eight by Ginsburg and Baker. Finally, in chapter nine, Abramson discusses several critical clinical considerations (e.g., the interpersonal) in the behavioral treatment of overweight individuals that often would be totally neglected by the neophyte therapist. The appendixes, including questionnaires, a behavioral contract, a physician's permission form, and illustrative case studies, are quite good. More of these would have enhanced the overall value of the book.

In summary, for the therapist interested in obtaining a rather quick idea as to what behavior therapists tend to do with their overweight patients, the book achieves its goal quite admirably. Moreover, the price is reasonable considering how inflation has affected the publishing business. However, in addition to the fact that some of the material is dated, I think the question of how successful patients are in maintaining their initial weight losses could have received more careful scrutiny. Then again, the book does reflect the current status of the art as it is being practiced. Despite deficiencies in our behavioral techniques, they represent the most successful of the psychotherapeutic approaches to the problem of overweight at this time.

Fragile Families, Troubled Children: The Aftermath of Infant Trauma, *by Elizabeth Elmer; Sue Evans and John B. Reinhart, co-investigators. Pittsburgh, Pa., University of Pittsburgh Press, 1977, 156 pp., $7.95.*

This book seeks to identify and compare 17 "abused" and 17 "accident" children at three different times: 1) when the infant was first brought to the attention of the study group, 2) one year later, and 3) eight years later. Various psychological and psychiatric examinations and thorough social work material were accumulated. Not the easiest task was the identification of abused children versus accident children. The latter were those seen with injuries or fractures that were presumably accidental, while the former were those whose parent or parents sporadically abused the child physically.

The initial chapter describes the study itself. Next is a chapter on the follow-up study and then one comprised of three case studies, each given in some detail. The final chapter presents the author's conclusions. In this chapter Elmer focuses on poverty: "By placing the results of our follow-up study in the context of the massive literature concerning poverty, we come to the conclusion that the results of child abuse are less potent for the child's development than class membership."

Actually, the author substantiates many well-known ideas about child abuse but is unable to confirm others. The two groups appear to be similar in many ways. Further studies and follow-up are planned, and this seems essential because the study reports on only a small sample of youngsters and their families. It shows some of the problems in choosing abused children and tries to deal with children so labeled who remain with their parents and those placed elsewhere.

This book was interesting to read, but I am left with the impression that much more needs to be done before we understand this complex problem. The study was begun before laws were enacted concerning child abuse and carried on after various laws were passed. As the author points out, for centuries children were dealt with as parents saw fit; it is only in fairly recent times that adults have begun to consider the rights of the child.

STUART M. FINCH, M.D.
Tucson, Ariz.

Psychosocial Treatment of Chronic Mental Patients: Milieu Versus Social-learning Programs, *by Gordon L. Paul and Robert J. Lentz. Cambridge, Mass., Harvard University Press, 1977, 514 pp., $22.50.*

This book is a report and an analysis in depth of a clinical research study designed to assess the relative effectiveness of traditional hospital management, milieu therapy, and a social learning program. The patient groups were carefully matched for age, sex, chronicity, length of hospitalization, and primary psychiatric diagnosis (all were diagnosed as schizophrenic). The severity of their functional impairment was such that all had been rejected for community placement in a previous screening.

Twenty-eight patients were assigned to each of three groups. The traditional treatment group was assessed periodically by the investigators, who tried to avoid having any influence on their management. This group essentially served as the controls in the study. The other two patient groups were placed in physically adjacent units at another location. A specially trained team of "change agents" worked with both groups in an alternating shift arrangement designed to make the treatment program itself the only significant variable.

The study (and the treatment programs) extended over a period of almost four and a half years. New patients (residents) were added as community placement, death, or other factors led to reduction of sample size. In all, 40 individuals were treated in the social learning program and 31 each in the milieu and hospital programs.

The authors do not consider the subjects of this study to be ill but, rather, to have learned inappropriate behaviors or to have failed to learn or to have forgotten behavior needed to function in a normal world. The two psychosocial rehabilitation programs are meticulously defined and described. Major objectives common to both are resocialization, instrumental role performance, reduction or elimination of extreme bizarre behaviors, and support in the community after release. The social learning program used a token economy and attempted to reduce undesirable behavior by ignoring it. The milieu program used both positive and negative feedback, with prompt and unambiguous response to both desirable and undesirable behaviors. Manuals for both programs are included in their entirety in this volume.

Criteria for release to the community until the last six months of the study required the capacity for independent functioning and self-support. In the final period community placement allowing board and care living arrangements was permitted. Under these modified conditions "significant release" required a continuous stay in the community of at least 90 days.

So many factors were assessed in this study that a summary of results in this review must be selective and incomplete. Release to independent functioning and self-support was achieved by 3 patients (residents) in the original social learning group, by 2 in the milieu group, and by one in the hospital group. Release to private extended care board and room facilities was achieved by all but 1 of the original social learning group, by two-thirds of the milieu group, and

by just under half of the hospital group. A cost effectiveness study showed a near-equal cost per patient per day in all three programs (a little more than $10) and a total cost over the four and a half years of about $15,000 for the social learning and milieu programs versus about $17,000 for the hospital program. Cost of psychotropic drugs over the four and a half years was about $1,072 for the hospital group versus $261 for the milieu and $147 for the social learning group. The authors conclude that psychotropic drugs were of little value in the psychosocial programs and may have had a negative effect in some instances.

This volume is much more than an account of treatment outcome comparing medical versus nonmedical approaches to schizophrenia. Other themes include an account of the problems growing out of funding delays and a description of difficulties caused by externally imposed (and seemingly arbitrary) changes in policy and practice. The imposition of a rule limiting seclusion for assaultive behavior to two hours (midway in the project) apparently led to an almost total loss of gains in the psychosocial treatment groups. Only by developing alternative "negative reinforcers" could these losses be recouped. The alternatives to prolonged seclusion or social isolation included heating and humidfying the seclusion room and introduction of a randomly activated klaxon horn. I found this maneuver disquieting, to say the least, particularly since the authors found some patients were committing minor "assaultive" acts for the "privilege" of having two hours of solitude.

I did not think that the results of the study prove that schizophrenia is a learned maladaptative lifestyle—nor do the authors specifically make such a claim. This is an important book, rich with carefully documented observations. It deserves a careful reading by all mental health professionals. The experimental design is a model of excellence. The book itself is exceptionally well crafted, with no evident technical flaws and a splendid index.

WILLIAM A. CANTRELL, M.D.
Houston, Tex.

Medical Information Systems: A Resource for Hospitals, *by Melville H. Hodge. Germantown, Md., Aspen Systems Corp., 1977, 192 pp., $16.75.*

This book is written at a most opportune time. The health professions are under increasing pressure from consumers and government alike to be accountable for their actions. There is growing impatience with the ever-increasing costs of medical care and demands that something be done to contain these costs.

In a very readable, well-outlined format, Mr. Hodge shows how a computerized medical information system can save hospitals money and increase efficiency. Some examples include economic benefits, conservatively estimated as saving from $3 to $5 per patient day by reducing errors, improving timeliness, and enhancing the availability of medical records. A medical information system can also provide more accurate data on personnel workloads, patient activity, and use of facilities. Mr. Hodge says that patient care improves because of the prevention of diagnostic and treatment errors. Finally, a medical information system, by collecting pertinent information, can be used in programs of research and education.

The book is divided into sections, beginning with a list of the theoretical and actual benefits in the areas of economy, patient care, research, and education. The next seciton deals with critical decisions that have to be made in setting up a medical information system—decisions that include what type of system is most suitable for a particular hospital and the measures that are necessary for the successful implementation of a system. Mistakes and errors in this area can be disastrous for the system and result in great financial losses for the hospital. The next section deals with the impact of a functioning system on the various hospital staff members and departments. Mr. Hodge concludes his book with a chapter on how a hospital can take steps to realize the benefits of a medical information system.

This book concerns medical information systems for general hospitals. Very little pertains directly to the functioning of psychiatrists in the system. However, in the hospitals with operational systems studied, psychiatrists were one of the groups of specialists that were in favor of the system. This was true in spite of the fact that they were the group who used the system least.

An issue not addressed by the author is that of confidentiality—what safeguards can be taken to protect patients from unauthorized persons obtaining information. If several hospitals became involved in a common medical information system the quesiton would become even more critical. Recent revelations in the press regarding the ease with which information can be obtained from systems specifically designed to be "burglar proof" are not reassuring. One hopes that the computer industry will give serious thought to how this problem can be resolved.

In conclusion, this book would be valuable to any organization contemplating installation of a medical information system. By his listing of the do's and don't's in such a process, Mr. Hodge shows how to avoid many of the potentially dangerous pitfalls.

GEORGE W. BARTHOLOW, M.D.
Omaha, Neb.

Therapeutic Partnership: Ethical Concerns in Psychotherapy, *by Carl Goldberg. New York, N.Y., Springer Publishing Co., 1977, 264 pp., $17.95.*

Dr. Goldberg's book represents a necessary inquiry that should be made by all persons involved in psychotherapeutic endeavors—a review of the basic assumptions on which psychotherapy is predicated and a pursuit of the implications of these assumptions in one's psychotherapy practice, education, training, and treatment. For the author, this assessment pivots on two presumably interconnecting themes: 1) the more circumscribed and concrete "client-therapist collaborative endeavors in establishing a therapeutic alliance" and 2) the larger and loftier "quest for meaning in human existence." The author believes that in the best of all psychotherapeutic worlds these two would be intimately related. The model of the book is existentially oriented and interpersonal and upholds the necessity of the presence of another person in realizing the autonomy of the self (i.e., the therapeutic centrality of relationship). It is a particular kind of relationship that Dr. Goldberg propounds, i.e., not the formation of the traditional therapeutic alliance but a "therapeutic partnership," not the more familiar working alliance but a "working contract." In essence, he posits an egalitarian and mutual partnership based on maximal informed consent of both parties (which may or may not be affirmed by a written contract), in which it is the client, not the therapist,

who in the final analysis defines health and illness. The book's subheading, *Ethical Concerns in Psychotherapy* refers not to the violation of existing moral or legal codes, which may be relatively easy to identify and deal with, but the more covert, subtle, and insidious departures from a hypothetical existential contract between client and therapist.

The philosophical stance of the book is highly relevant—an apt expression of the growing consciousness of human rights and responsibilities, evident in the current interest in patients' rights and power relations. Despite this theoretical vantage point, the author actively addresses the reputed failure of existentially oriented psychotherapists to depict the therapeutic encounter in other other than poetic or metaphysically vague terms. This is well countered by the author's careful attention to specific and practical aspects of the therapist-client relationship in its immediate applications. The vicissitudes of encounter issues in practice, to which a major portion of the book is devoted, are well developed in separate chapters of considerable breadth, each reflecting a different modality or therapeutic situation, e.g., marital therapy, cotherapy, group therapy, encounter groups, the therapeutic community, community mental health programs, and consultation. In addition, a rather unprecedented appendix provides (for therapist as well as client) "A Client Guide to Selecting a Therapist and Formulating a Therapeutic Contract."

Dr. Goldberg aspires to close the reputed gap between therapist and patient through mutual enlightenment, but it is clear throughout the book which side he takes. By obliterating the distance between the two therapeutic parties Dr. Goldberg means to restore power to the client from the presumably dominating, abusive hands of the traditional psychotherapist, whose subversive purposes he hopes to "demystify" and "demedicalize." Stirred by this strong client advocacy position, Dr. Goldberg relentlessly opts for "power adequacy"—rational (i.e., equitable) use of power in the therapeutic enterprise.

Although this is an undisputedly commendable goal as such, it is sometimes confused in its articulation with a rejection of all psychiatry, medicine, or psychotherapy as previously practiced. The fact that Dr. Goldberg chose Thomas Szasz to write his preface implies that he is the person to whom Dr. Goldberg's major allegiance lies. This may be an unduly limiting alliance because we are thus given to believe that the antipsychiatry postulates that mental illness and mental treatment are myths are prerequsites to our thinking, in that they provide the philosophical backbone of Dr. Goldberg's treatise. This is unfortunate because the author already feels that he has lost a potential audience of "experienced practitioners" who may not be amenable to questioning the premises of their work. Actually, the book will probably be of more extensive value than Dr. Goldberg assumes if read by those with or without strict subscription to the Szaszian framework.

There are two other ways in which this stance may be misleading. First, it has not been definitively determined as yet what therapeutic roles are played in the therapeutic process by the curer's charisma, ambiguity or mystique, or the use of magic and faith. These elements have always been vital parts of the therapeutic endeavor. Second, Dr. Goldberg's statement that "the therapist must teach the client how to rationally use his power or how to regain his low power" (p. 97) may be a contradiction in terms that serves only to compound the problem, i.e., power is being put back into the hands of the very therapists who presumably possessed it in the first place.

Despite statements of this kind, which may be reflective only of the ardor with which Dr. Goldberg pursues his point, *Therapeutic Partnership* is a highly readable piece of work. It adroitly avoids the inherent danger in writing about ethical matters—that of appearing moralistic or above reproach. In general, the author keeps a good balance between well-referenced research studies and an ample supply of case examples and anecdotal material; these are useful and of interest to therapist and client alike. Sometimes, however, Dr. Goldberg seems to have trouble straddling the needs of both parties, vacillating between the theoretical and pragmatic, the scholarly and the mundane. Moreover, in his ideal attempt to address the client and therapist as equals, he often overcompensates the client by portraying the therapist in too negative a light (by recounting instances of the very order he says he intends to avoid, e.g., moral improprieties involving sex relations, overcharging of fees, and nudity). However, all of this may be an inevitable concomitant of a truly ambitious and arduous task, to accomplish in writing what he hopes to accomplish in the therapeutic relationship, a partnership of client and therapist in which unspoken and alienating differences are ultimately united by their common concerns.

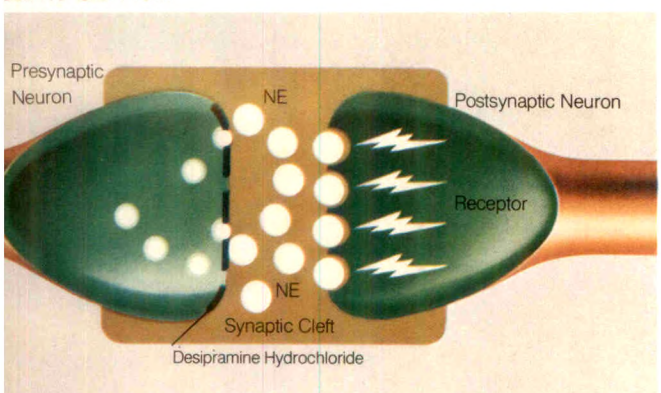
When your patient is clinically depressed...
"...everything I saw was negative."

(Electron micrograph of human synaptic cleft.)



...consider this potent blocker of norepinephrine re-uptake

The biogenic amine hypothesis states that depression may be associated with a deficiency of specific neurotransmitters—norepinephrine or serotonin—at brain receptor sites.[1] Tricyclics appear to block the re-uptake of specific neurotransmitters. Some tricyclics specifically block the re-uptake of serotonin; others block the re-uptake of norepinephrine.[2] Therefore, if your patient is unresponsive to treatment with one tricyclic, consider switching to a tricyclic which blocks the re-uptake of a different neurotransmitter.

Norpramin®
(desipramine hydrochloride tablets NF)
25, 50, 75, 100, 150 mg.

Potent blocker of norepinephrine re-uptake

According to current theory[1,3] some tricyclic antidepressants may fail in certain types of depression because they are not sufficiently potent blockers of norepinephrine re-uptake. Laboratory studies have shown that desipramine is the most potent inhibitor of norepinephrine re-uptake.[4] Norpramin may work in some patients when other tricyclic antidepressants do not.

Consider it now, consider it next.

Less anticholinergic activity

(See Warnings section.)

Studies in animals[5] and in normal human subjects[6,7] have shown that desipramine has significantly less anticholinergic activity than amitriptyline or doxepin. The single bond side chain is associated with lower anticholinergic activity than these other leading antidepressants. This may mean:

- less dry mouth
- less blurred vision
- less urinary retention

Helps patients remain calm but active

Norpramin does not usually inhibit normal activity although patients should be cautioned as to driving or operating machinery if drowsiness occurs.

In addition...

Begins to improve sleep patterns within one week in some patients[8]

- Norpramin helps relieve the sleep disturbances that often accompany depression.
- As the depression is relieved, the difficulty in falling asleep, restlessness, and early morning awakening diminish.

(For prescribing information see next page.)

Merrell

Now 300 mg. dosage range broadens clinical flexibility

A maximum dosage of 300 mg. a day, as a single or divided dose, may now be prescribed for Norpramin. Since inadequate dosage is thought to be one of the major causes of treatment failure, the new therapeutic range should prove clinically helpful. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Norpramin®
(desipramine hydrochloride tablets NF)

AVAILABLE ONLY ON PRESCRIPTION

Brief Summary

MECHANISM OF ACTION: Available evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters such as norepinephrine and serotonin. Norepinephrine deficiency may be associated with relatively low urinary 3-methoxy-4-hydroxyphenyl glycol (MHPG) levels, while serotonin deficiencies may be associated with low spinal fluid levels of 5-hydroxyindolacetic acid.

While the precise mechanism of action of the tricyclic antidepressants is unknown, a leading theory suggests that they restore normal levels of neurotransmitters by blocking the re-uptake of these substances from the synapse in the central nervous system.

Evidence indicates that the secondary amine tricyclic antidepressants, including Norpramin, may have greater activity in blocking the re-uptake of norepinephrine. Tertiary amine tricyclic antidepressants, such as amitriptyline, may have greater effect on serotonin re-uptake.

Norpramin (desipramine hydrochloride) is not a monoamine oxidase (MAO) inhibitor and does not act primarily as a central nervous system stimulant. It has been found in some studies to have a more rapid onset of action than imipramine. Earliest therapeutic effects may occasionally be seen in 2 to 5 days, but full treatment benefit usually requires 2 to 3 weeks to obtain.

INDICATIONS: Norpramin (desipramine hydrochloride) is indicated for relief of symptoms in various depressive syndromes, especially endogenous depression.

CONTRAINDICATIONS: Desipramine hydrochloride should not be given in conjunction with, or within 2 weeks of, treatment with an MAO inhibitor drug; hyperpyretic crises, severe convulsions, and death have occurred in patients taking MAO inhibitors and tricyclic antidepressants. When Norpramin (desipramine hydrochloride) is substituted for an MAO inhibitor, at least 2 weeks should elapse between treatments. Norpramin should then be started cautiously and should be increased gradually.

The drug is contraindicated in the acute recovery period following myocardial infarction. It should not be used in those who have shown prior hypersensitivity to the drug. Cross sensitivity between this and other dibenzazepines is a possibility.

WARNINGS: 1. Extreme caution should be used when this drug is given in the following situations: a. In patients with cardiovascular disease, because of the possibility of conduction defects, arrhythmias, tachycardias, strokes, and acute myocardial infarction. b. In patients with a history of urinary retention or glaucoma, because of the anticholinergic properties of the drug. c. In patients with thyroid disease or those taking thyroid medication, because of the possibility of cardiovascular toxicity, including arrhythmias. d. In patients with a history of seizure disorder, because this drug has been shown to lower the seizure threshold. **2.** This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. **3.** USE IN PREGNANCY: Safe use of desipramine hydrochloride during pregnancy and lactation has not been established; therefore, if it is to be given to pregnant patients, nursing mothers, or women of childbearing potential, the possible benefits must be weighed against the possible hazards to mother and child. Animal reproductive studies have been inconclusive. **4.** USE IN CHILDREN: Norpramin (desipramine hydrochloride) is not recommended for use in children since safety and effectiveness in the pediatric age group have not been established. **5.** The patient should be cautioned that this drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. **6.** In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage.

PRECAUTIONS: 1. It is important that this drug be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with this class of drug. Ordinary prudence requires that children not have access to this drug or to potent drugs of any kind; if possible this drug should be dispensed in containers with child-resistant safety closures. Storage of this drug in the home must be supervised responsibly. **2.** If serious adverse effects occur, dosage should be reduced or treatment should be altered. **3.** Norpramin (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates. **4.** The drug may cause exacerbation of psychosis in schizophrenic patients. **5.** Close supervision and careful adjustment of dosage are required when this drug is given concomitantly with anticholinergic or sympathomimetic drugs. **6.** Patients should be warned that while taking this drug their response to alcoholic beverages may be exaggerated. **7.** Clinical experience in the concurrent administration of ECT and antidepressant drugs is limited. Thus, if such treatment is essential, the possibility of increased risk relative to benefits should be considered. **8.** The sedative effects of Norpramin and benzodiazepines (*e.g.*, chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. **9.** This drug should be discontinued as soon as possible prior to elective surgery because of the possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients taking desipramine hydrochloride. **10.** Both elevation and lowering of blood sugar levels have been reported. **11.** Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

ADVERSE REACTIONS: Note: Included in the following listing are a few adverse reactions that have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when Norpramin (desipramine hydrochloride) is given.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic: numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus.

Anticholinergic: dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis, increased intraocular pressure; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs.

Hematologic: bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue.

Endocrine: gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

DOSAGE AND ADMINISTRATION: Not recommended for use in children. Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients compared to hospitalized patients, who are closely supervised. Dosage should be initiated at a low level and increased according to clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a period of time and should be at the lowest dose that will maintain remission.

Usual Adult Dose: The usual adult dose is 100 to 200 mg. per day. In more severely ill patients, dosage may be further increased gradually to 300 mg./day if necessary. Dosages above 300 mg./day are not recommended.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response.

Treatment of patients requiring as much as 300 mg. should generally be initiated in hospitals, where regular visits by the physician, skilled nursing care, and frequent electrocardiograms (ECG's) are available.

The best available evidence of impending toxicity from very high doses of Norpramin is prolongation of the QRS or QT intervals on the ECG. Prolongation of the PR interval is also significant, but less closely correlated with plasma levels. Clinical symptoms of intolerance, especially drowsiness, dizziness, and postural hypotension, should also alert the physician to the need for reduction in dosage. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

Adolescent and Geriatric Dose: The usual adolescent and geriatric dose is 25 to 100 mg. daily.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response to a usual maximum of 100 mg. daily. In more severely ill patients, dosage may be further increased to 150 mg./day. Doses above 150 mg./day are not recommended in these age groups.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

OVERDOSAGE: See prescribing information for a discussion of symptoms and treatment of overdose.

Product Information as of April, 1978

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

CALM
AND
ALERT*
THE
PATIENT ON
VERSTRAN®
(prazepam)
C IV

Smooth, consistent anxiolytic action is the reason.

Proven efficacy

- Effective symptomatic relief of anxiety, whether psychic or somatic in origin
- Therapeutic response achieved with first dose
- Verstran—a suitable antianxiety alternative to diazepam

Established safety

- Virtually no drowsiness* in most Verstran patients (less than 10%)
- Other side effects, if present, are minimal†
- Verstran is appropriate concomitant therapy in most somatic disorders‡
- No accumulation after steady state is reached

Dosage versatility

- The simplicity of a single-strength 10-mg scored tablet, for easy titration and improved patient compliance
- The flexibility of *once daily*§ dosage
- The option of a *b.i.d.* dosage regimen, gradually adjustable within a range of 20 to 60 mg/day

*As with all CNS-acting agents, patients should be cautioned against driving, drinking, or engaging in hazardous activities.

†Data on file, Warner/Chilcott Medical Department.

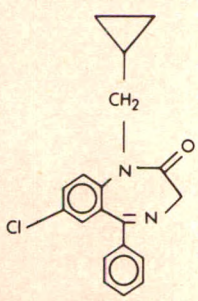
§At bedtime.

TO ENHANCE PATIENT RESPONSIVENESS CONSIDER



VERSTRAN®

(prazepam) Ⓒ IV

VERSTRAN® (prazepam) Ⓒ IV

Caution: Federal law prohibits dispensing without prescription.

Description: Verstran (prazepam), a benzodiazepine derivative, is identified chemically as 7-chloro-1-(cyclopropylmethyl)-1,3-dihydro-5-phenyl-2H-1,4-benzodiazepin-2-one. The molecular weight is 324.8 and the structural formula is as follows:

Clinical Pharmacology: Studies in normal subjects have shown that Verstran (prazepam) has depressant effects on the central nervous system. Oral administration of single doses as high as 60 mg and divided doses up to 100 mg t.i.d. (300 mg total daily dose) were without toxic effects.

Single oral doses of Verstran in normal subjects produced peak blood levels at 6 hours postadministration, with significant amounts still present after 48 hours. Verstran was slowly absorbed over a prolonged period, rather constant blood levels were maintained, and excretion was prolonged. The mean half-life of prazepam measured in subjects given 10 mg b.i.d. for one week was 63 (±15 s.d.) hours before and 70 (±10 s.d.) hours after multiple dosing — a nonsignificant difference. Human metabolism studies showed that prior to elimination from the body, prazepam is metabolized in large part to 3-hydroxyprazepam and oxazepam.

Indications: Verstran (prazepam) is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

The effectiveness of Verstran (prazepam) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

Contraindications: Verstran (prazepam) is contraindicated in patients with a known sensitivity to the drug and in those with acute narrow angle glaucoma.

Warnings: Verstran (prazepam) is not recommended in psychotic states and in those psychiatric disorders in which anxiety is not a prominent feature.

Patients taking Verstran should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery, including motor vehicles.

Because Verstran has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, including phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The effects of alcohol may also be increased.

Physical and Psychological Dependence: Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepine drugs. These symptoms include convulsions, tremor, abdominal and muscle cramps, vomiting and sweating. Addiction-prone individuals, such as drug addicts and alcoholics, should be under careful surveillance when receiving benzodiazepines because of the predisposition of such patients to habituation and dependence.

Precautions:

Use in Pregnancy and Lactation:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Verstran (prazepam) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug. In view of their molecular size, Verstran and its metabolites are probably excreted in human milk. Therefore, this drug should not be given to nursing mothers.

In those patients in whom a degree of depression accompanies the anxiety, suicidal tendencies may be present, and protective measures may be required. The least amount of drug that is feasible should be available to the patient at any one time.

Patients taking Verstran for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed. Hepatomegaly and cholestasis were observed in chronic toxicity studies in rats and dogs.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

Pediatric Use: Safety and effectiveness in patients below the age of 18 have not been established.

Adverse Reactions: The side effects most frequently reported during double-blind placebo-controlled trials employing a typical 30 mg divided total daily dose and the percent incidence in the Verstran (prazepam) group were: fatigue (11.6%), dizziness (8.7%), weakness (7.7%), drowsiness (6.8%), lightheadedness (6.8%), and ataxia (5.0%). Less frequently reported were: headache, confusion, tremor, vivid dreams, slurred speech, palpitation, stimulation, dry mouth, diaphoresis, and various gastrointestinal complaints. Other side effects included: pruritus, transient skin rashes, swelling of feet, joint pains, various genitourinary complaints, blurred vision, and syncope. Single nightly dose, controlled trials of variable dosages showed a dose-related incidence of these same side effects. Transient and reversible aberrations of liver function tests have been reported, as have slight decreases in blood pressure and increases in body weight.

These findings are characteristic of benzodiazepine drugs.

Overdosage: As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

If vomiting has not occurred spontaneously, it should be induced. Immediate gastric lavage is also recommended. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though unlikely, may be controlled with Levophed® (levarterenol bitartrate) or Aramine® (metaraminol bitartrate). Caffeine and Sodium Benzoate Injection, USP, may be used to counteract central nervous system depressant effects.

Dosage and Administration: Verstran (prazepam) is administered orally in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 20 to 60 mg daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a divided daily dose of 10 mg to 15 mg. (See Precautions.)

Prazepam may also be administered as a single dose daily at bedtime. The recommended starting nightly dose is 20 mg. The response of the patient to several days' treatment will permit the physician to adjust the dose upward or, occasionally, downward to maximize antianxiety effect with a minimum of daytime drowsiness. The optimum dosage will usually range from 20 to 40 mg.

Drug Interactions: If Verstran (prazepam) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If Verstran is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

How Supplied: Verstran (prazepam) 10 mg light blue, scored tablets in bottles of 100 (N 0047-0276-51) and 1000 (N 0047-0276-60).

STORE BETWEEN 59°–86° F (15°–30° C).

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

Divide scored Endep tablets

+

Add flexibility to dosage titration

Long term treatment of depression with amitriptyline requires precise calculation of dosage to meet the individual needs of each patient. Because all six strengths of Endep are scored, you can easily increase or decrease dosage in half-tablet steps, without the bother and expense of a new prescription.

−

Subtract waste and cost

Scored Endep tablets permit you to adjust the regimen without wasting unused tablets or burdening the patient with the cost of a new prescription.

×

Multiply therapeutic options

The pharmacokinetic properties of Endep are such that its clinical effect is the same whether prescribed *t.i.d.* or as a single daily dose. Thus, once you have established the proper dosage, you can prescribe the entire dose *h.s.*, minimizing anticholinergic and sedative side effects, and helping to assure patient compliance with this simple regimen.

By prescribing the higher strength tablets *h.s.*— secure in the knowledge that the dosage can be adjusted without resorting to a new prescription—your patient will economize further on a per milligram basis.

Endep®

amitriptyline HCl/Roche

The only antidepressant scored for easy division

Endep
amitriptyline HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Supplied: *Scored Tablets:* 10, 25, 50, 75, 100, 150 mg.

Molindone HCl

Lidone™ treats the classic target symptoms

with less likelihood of certain troublesome effects

Prescribing Information for

Lidone™ (molindone hydrochloride)

DESCRIPTION — LIDONE (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

LIDONE is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4(5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

ACTIONS — LIDONE (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, LIDONE antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, LIDONE exerts its effect on the ascending reticular activating system.

Human metabolic studies show LIDONE (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24 to 36 hours. There are 36 recognized metabolites with less than 2 to 3% unmetabolized LIDONE being excreted in urine and feces.

INDICATIONS — LIDONE (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS — LIDONE (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats Oral Dose —
20 mg/kg/day — 10 days, no adverse effect
40 mg/kg/day — 10 days, no adverse effect

Pregnant Mice Oral Dose —
20 mg/kg/day — 10 days, slight increase resorptions
40 mg/kg/day — 10 days, slight increase resorptions

Pregnant Rabbits Oral Dose —
5 mg/kg/day — 12 days, no adverse effect
10 mg/kg/day — 12 days, no adverse effect
20 mg/kg/day — 12 days, no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of LIDONE (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of LIDONE (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS — Some patients receiving LIDONE (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving LIDONE. Caution should be exercised where increased activity may be harmful.

LIDONE does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

LIDONE has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS

CNS Effects — The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological Extrapyramidal Reactions — Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia — Motor restlessness may occur early.

Parkinson Syndrome — Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome — Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System — Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological — There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with LIDONE may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects — Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with LIDONE therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with LIDONE.

Cardiovascular — Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological — Lens opacities and pigmentary retinopathy have not been reported where patients have received LIDONE (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with LIDONE.

Skin — Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with LIDONE usage alone.

LIDONE (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when LIDONE is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia — Although rarely reported with LIDONE (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION — Initial and maintenance doses of LIDONE (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50 to 75 mg/day.
- — Increase to 100 mg/day in three or four days.
- — Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- — An increase to 225 mg/day may be required in patients with severe symptomatology.
- — Some chronic, treatment-resistant patients may require up to 400 mg/day; (however, the long-term safety of 400 mg/day has not been established).

Elderly or debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild — 5 mg to 15 mg three or four times a day.
2. Moderate — 10 mg to 25 mg three or four times a day.
3. Severe — 225 mg/day may be required.

Dosage may be administered once a day.

DRUG INTERACTIONS — Potentiation of drugs administered concurrently with LIDONE (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when LIDONE is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE — Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of LIDONE (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of LIDONE (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by LIDONE in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized LIDONE from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of LIDONE is excreted unmetabolized in the urine.) However, poor response of the patient may justify use of these procedures.

While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized LIDONE in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED — LIDONE (molindone hydrochloride) capsules are supplied in bottles of 100 in the following dosage strengths and colors:

5 mg (**NDC** 0074-5542-13) blue and cream
10 mg (**NDC** 0074-5543-13) red and cream
25 mg (**NDC** 0074-5544-13) brown and cream

Lidone lets you control key schizophrenic symptoms,

- **Significant gains have been reported** following use of Lidone for patients experiencing hallucinations, conceptual disorganization, hostility, unusual thought content, and other schizophrenic manifestations.
- **Progress has also been noted** in the social outlook of patients. Emotional withdrawal has lessened with the Lidone therapy. Many patients have improved their social behavior and interpersonal relationships.

yet keep a low side effects profile

- **There have been no reports of persistent** tardive dyskinesia, excessive weight gain, impotence, lens opacities, or skin pigmentation. And the incidence of significant hypotension is rare (below 1% in clinical studies). Other side effects are similar to comparable agents, and seldom require discontinuation of therapy.

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

In depression...

3 of 10 patients will fail to respond to initial therapy.

make

PERTOFRANE® (desipramine HCl NF)

your first choice for the 3 of 10 patients who don't respond.

because of:

- **CLINICAL EFFECTIVENESS** even when "most patients had a history of several depressive episodes, hospitalizations, ECT or poor response to numerous other drugs."[1]

- **LOW SIDE EFFECTS PROFILE** with less sedating properties than amitriptyline or doxepin[2] and less anticholinergic activity.[3]

- **ENHANCED PATIENT ACCEPTANCE** through a flexible dosage schedule plus rapid onset of action.

PERTOFRANE® when they don't respond.
(desipramine HCl NF)

USV LABORATORIES
USV Laboratories Inc.
Manati, P.R. 00701

Please see next page for brief summary of prescribing information and references.

PERTOFRANE®
(desipramine HCl NF)

Indication: For relief of mental depression. **Contraindications:** Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane (desipramine HCl) in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. The potentiation resulting from excessive use of alcohol may increase the danger inherent in a suicide attempt or overdosage. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine. **Dosage:** All patients except geriatric and adolescent: 75 to 150 mg./day in divided doses or as single daily dose. Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Therapy may be given in divided doses or as a single daily dose. **How Supplied:** 25 mg. capsules (pink), bottles of 100 and 1000. Also, 50 mg. capsules (maroon and pink), bottles of 100 and 1000.

DIRECTOR OF HEALTH
SALARY TO $42,000

Fresno County is searching for a capable executive to manage the diverse and complex activities of the Health Department. Basically, there are three top level managers reporting to the Director: The Health Officer, The Associate Director for Administration matters, and the Mental Health Chief. The Health Department employs approximately 764 people with an operating budget of $20,017,703.00 Combining public health and mental health operations, the Department prides itself in the use of innovative approaches to provide integrated health services through a program of decentralized care.

Warm, dry summers and mild winters generally characterize the area's climate. A number of fine schools, a state university, and several community colleges contribute to the intellectual aspects of the community. Yosemite, Kings Canyon, and Sierra National Parks are no more than two hours away. Carmel and other picturesque coastal areas are within three hours easy drive. Excellent housing is available in several different areas at price levels lower than other metropolitan areas of California and many parts of the United States.

Professional Administrators should consider the opportunity providing they have at least five years of high level management experience in the Health Administration field.

We would be pleased to answer your questions. Contact Lonnie Hayhurst, Chief, Recruitment & Employment, 2220 Tulare Street, 3rd Floor Townehouse, Fresno, California 93721; Phone: (209) 488-3364.

PKSAP-III

PSYCHIATRIC KNOWLEDGE AND SKILLS SELF-ASSESSMENT PROGRAM

CONTINUOUS OFFERING

PKSAP-III is again available. The Program, initially available to physicians in Spring/Summer, 1977, will differ in that central scoring services will not be provided. Each registrant will receive the question booklets, the Reference guidebook containing the correct answers and bibliography, a score worksheet, and the Performance Data Report, which will facilitate self-scoring, follow-up reading and study at the participant's convenience. For further program details, the Bulletin of Information, is available upon request to the APA, Office of Education.

To register, remit the appropriate fee with this application form to the APA, PUBLICATIONS SALES. PLEASE MAKE CHECKS PAYABLE TO APA, PKSAP-III.

They thought Ed Sloan was just tired...

maybe he had narcolepsy

A narcoleptic can fall asleep almost anywhere, anytime. The results can be at least embarrassing...at most devastating.

Narcolepsy is often unrecognized

As a primary sleep abnormality narcolepsy is characterized by sleepiness, inappropriate sleep episodes, and cataplexy (episodes of muscular weakness precipitated by strong emotion). These are often accompanied by hypnagogic hallucinations, automatic behavior and/or disturbed nocturnal sleep. Sleep apnea may be a severe life-threatening complication of narcolepsy.

Besides its medical implications, narcolepsy may have drastic social consequences.

"All too often, the patient with disabling hypersomnolence is ignored by physicians for years and even decades, with the consequent tragic toll on his ability to learn and to work."[1]

Ritalin can help in narcolepsy

For narcoleptic sleepiness and sleep episodes, the cited authorities[1,2] most frequently use Ritalin (methylphenidate).

For the 200,000 narcoleptics who can't stay awake

Please turn page for brief prescribing information.

Ritalin® (methylphenidate) C II

For the 200,000 narcoleptics who can't stay awake

Ritalin® hydrochloride C II
(methylphenidate hydrochloride USP)
TABLETS

INDICATION
Narcolepsy.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.

Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.

DIRECTOR, PSYCHIATRIC DAY HOSPITAL PROGRAM —

200-Bed non-profit community Hospital situated in a New England shore city, one hour from New York City, seeks a Psychiatrist or Psychologist to participate in the development and provide clinical supervision of this new program. The position will be twenty hours per week, Hospital currently operates an inpatient mental health unit. Excellent salary and benefit program. Send resume to include salary history and requirements to:

P.O. Box AJP-847
American Journal of Psychiatry
Advertising Department
American Psychiatric Association
1700 18th St., N.W.
Washington, D.C. 20009

DIRECTOR OF MENTAL HEALTH FOR THE STATE OF MICHIGAN

Immediate opening for Director of the State Mental Health Department of Michigan with 14,000 employees, a budget of more than $400 million, and direct responsibility for 25 facilities for the mentally ill and developmentally disabled. Progressive state with concerned citizenry, a supportive legislature and excellent mental health law. Statutory requirement: at least 5 years of executive experience in Mental Health. Search Committee will recommend candidates to the Governor, who appoints the Director subject to confirmation by the State Senate. The Director serves at the pleasure of the Governor. Salary is $47,700 with full fringe benefits. Send resume by October 15th to:

Mary Rave, Chairperson
Search Committee
3600 Geddes Road
Ann Arbor, Michigan 48105

Michigan is an Affirmative Action/Equal Opportunity Employer

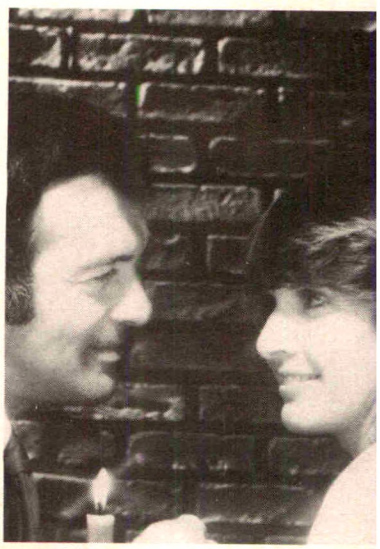
IMMEDIATE OPENING: ASSISTANT DIRECTOR FOR DEVELOPMENTAL DISABILITIES

Responsible for organizing and directing the planning, implementation, and coordination of an area-wide, community-based comprehensive mental retardation/developmental disabilities program in a community Mental Health Center serving 7 rural counties in Northwestern Minnesota. Activities include the provision of client centered, program centered and administrative consultation to MR/DD service providers; the development of a biennial area MR/DD program plan; and provision of direct outpatient services to developmentally disabled individuals and their families. Qualifications include a masters degree in social work or other related discipline with significant proven experience and knowledge of MR/DD delivery systems. Send resume and three references to Roy Waters, MA, ACSW, Area Program Director, Northwestern Mental Health Center, Box 603, Crookston, MN 56716, or call (218) 281-3940.

AN EQUAL OPPORTUNITY EMPLOYER

MEDICAL SUPERINTENDENT

The Missouri Department of Mental Health is seeking superintendents for a large and a medium size state hospital at St. Louis State Hospital, St. Louis, Missouri, and Farmington State Hospital, Farmington, Missouri, respectively. These are administrative and medical positions involving treatment of patients and hospital operations for professional and hospital support staffs. Qualifications include certification or proof of eligibility for certification in psychiatry by the American Board of Psychiatry and Neurology or completion of five-year psychiatric career residency program of the Missouri Department of Mental Health, supplemented by three years of clinical experience in psychiatry in an approved hospital or clinic for the mentally ill or in an institution for the mentally retarded, of which one year must have been in a supervisory or administrative capacity. Substitution for these qualifications will be given to a valid certificate issued by the American Psychiatric Association Committee on Certification of Mental Hospital Administrators or possession of a specialty board certificate issued by the American Medical Association or American Osteopathic Association, supplemented by five years of administrative experience as a Clinical Director, Medical Director, Assistant Medical Director or Chief of Staff at an approved hospital or center serving mentally ill, developmentally disabled or substance abuse patients. Qualifying certificates issued by other countries may be acceptable on an individual basis. Applicants must be able to secure a license to practice medicine in the State of Missouri. Annual salary range is $48,127 to $55,422, plus housing.



SEND CURRICULUM VITAE/RESUME TO: C. Duane Hensley, Ph.D., Director, Department of Mental Health, 2002 Missouri Boulevard, Jefferson City, Missouri 65101, or Henry V. Guhleman, Jr., M.D., Director, Division of Comprehensive Psychiatric Services, Department of Mental Health, 2002 Missouri Boulevard, Jefferson City, Missouri 65101 (314/751-3944).

Merck Sharp & Dohme announces a new dosage strength

now dual-action® Triavil® 4-50

containing 4 mg perphenazine and 50 mg amitriptyline HCl

For even more dosage versatility in the treatment of marked agitation with depression

NEW dosage strength—to simplify therapy
five dosage strengths now available

NEW option: b.i.d. regimen—to improve compliance
for initiating therapy
Rx TRIAVIL 4-50 b.i.d.

NEW unit-of-use package
bottles of 60 for 30 days of therapy, where appropriate

When TRIAVIL is part of the program, you may anticipate these therapeutic benefits for many patients:

Rapid antianxiety effect
The tranquilizer component can alleviate symptoms of anxiety and agitation within a few days. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active.

Highly effective antidepressant action
The antidepressant component can help relieve symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

...to aid the psychotherapeutic process
Patients often become more accessible and cooperative; symptomatic relief may enable the patient to function more effectively in his daily activities.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks such as operating machinery or driving. The drug may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

Please see following page for a brief summary of prescribing information.

For a wide range of patients with marked agitation and depression

dual-action Triavil®
containing perphenazine and amitriptyline HCl

now offers more dosage strengths than any other formulation containing a tranquilizer and an antidepressant

dual-action Triavil®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MERCK SHARP & DOHME

ASSISTANT SUPERINTENDENT FOR PROFESSIONAL SERVICES

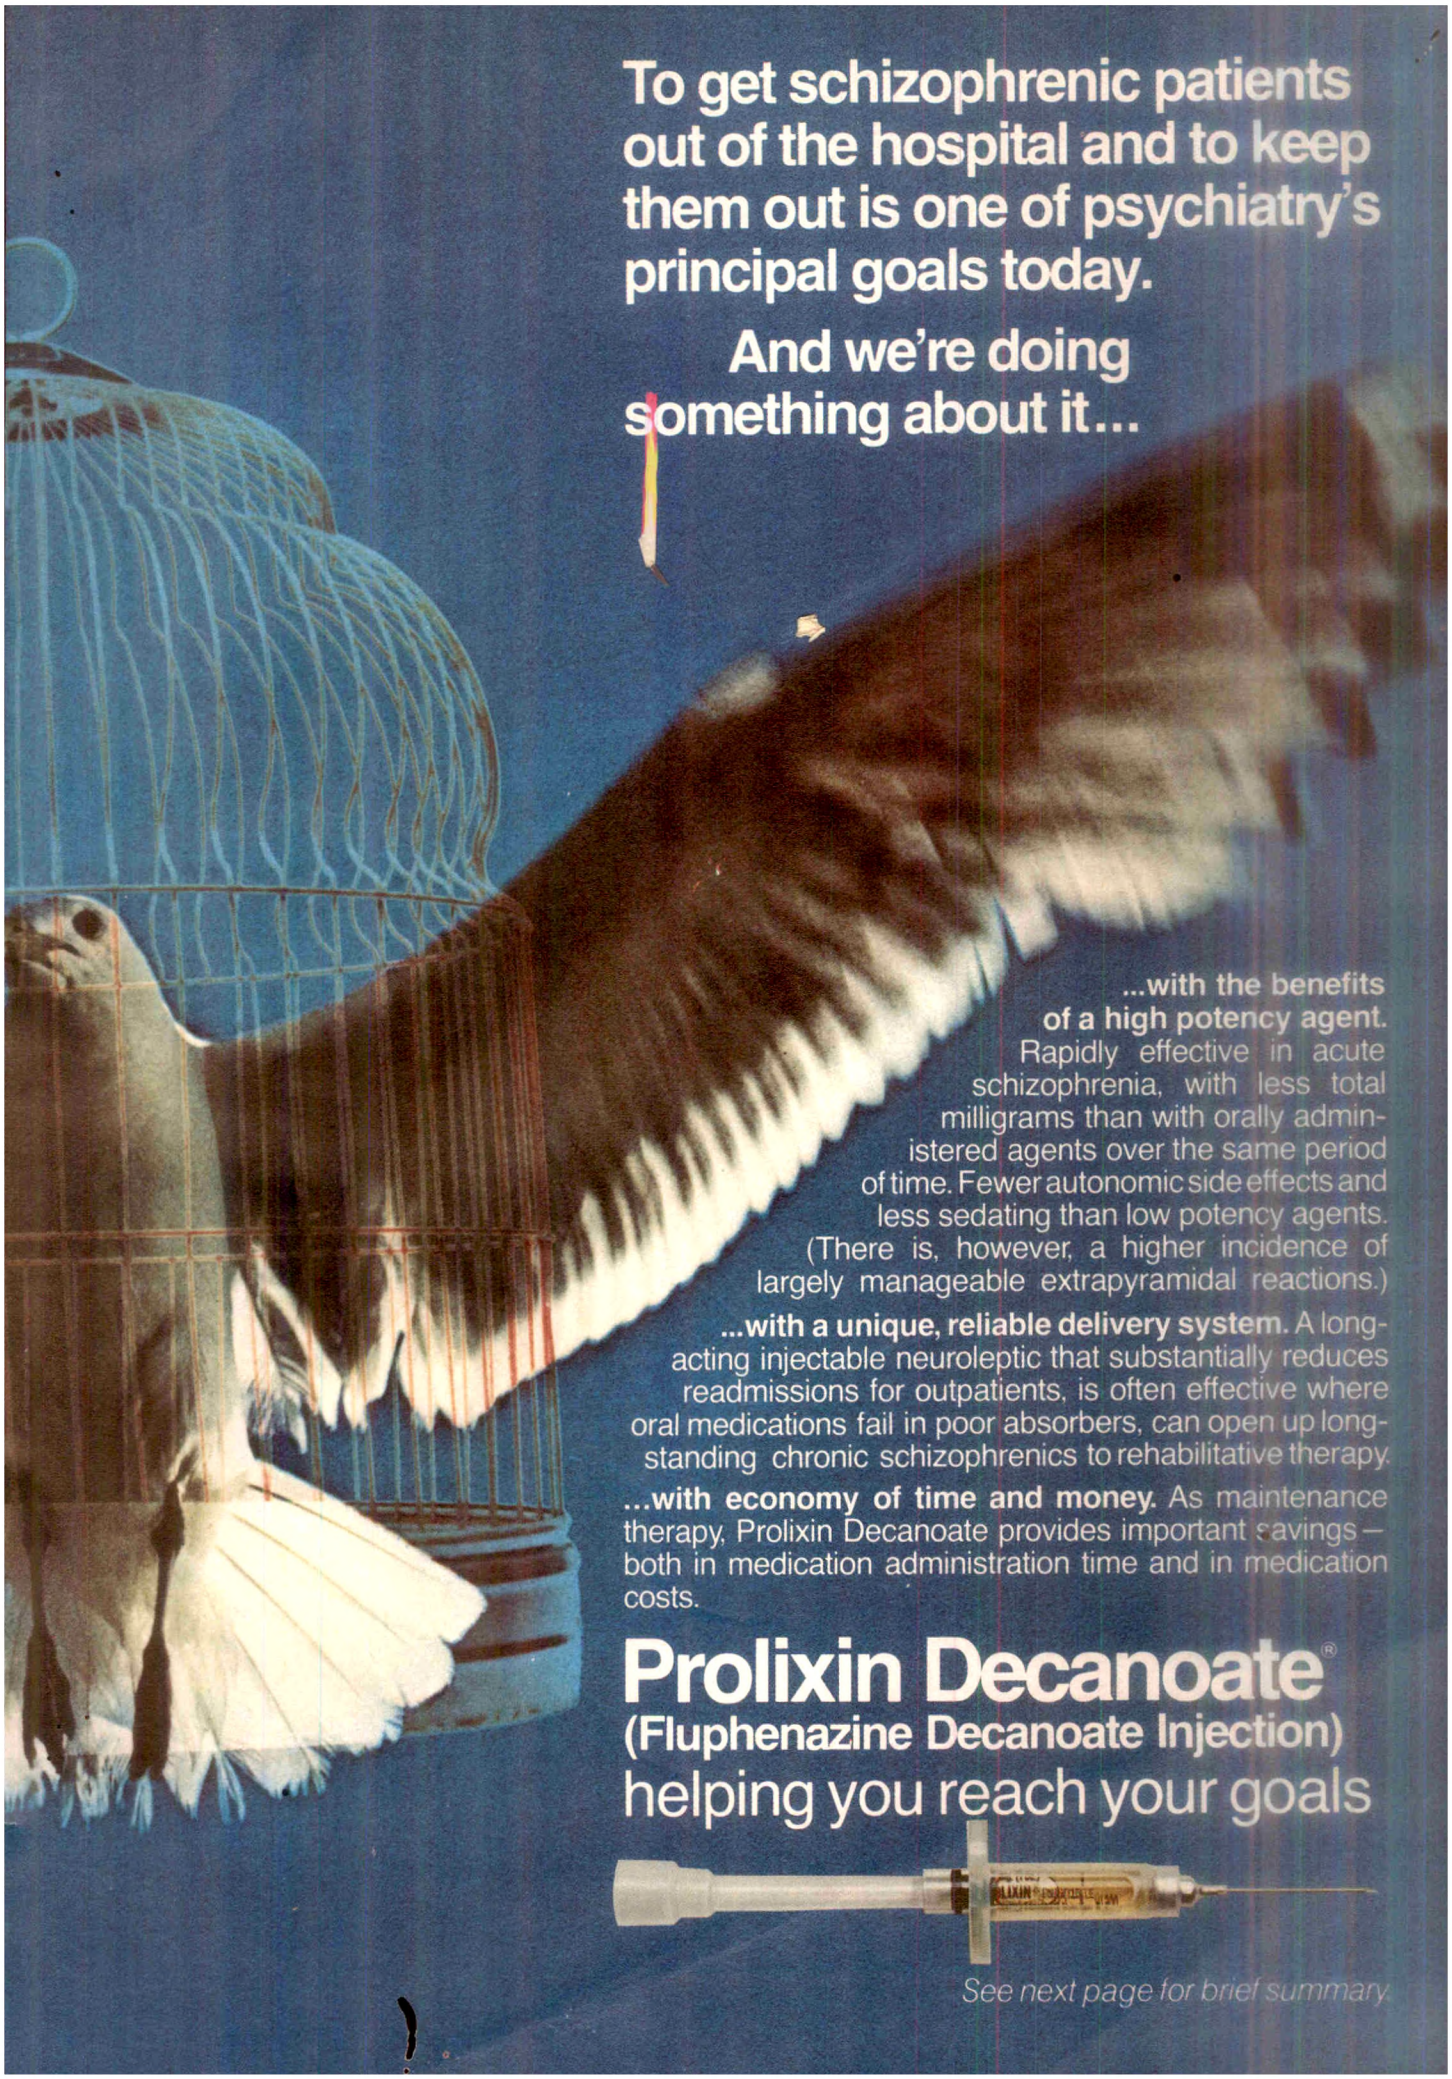
New Hampshire Hospital, Concord, N.H., an 800 bed JCAH-Accredited psychiatric hospital, is seeking an Assistant Superintendent for Professional Services to be responsible for the direction and coordination of clinical programs for the treatment, care and management of mentally ill patients. New Hampshire Hospital, the only public psychiatric hospital in N.H., is located in Concord, a city of approximately 30,000 people, 75 minutes north of Boston, MA. Salary ranges from $30,740-$38,690, plus an additional $3,000 per year if board certified. Possibility of faculty appointment to major university. Housing and other fringe benefits are available. Candidate must be a physician-psychiatrist licensed or eligible for licensure as an M.D. in New Hampshire and certified or eligible for certification by the American Board of Neurology and Psychiatry.

Interested applicants should contact C. Clifton DuBois, Ph.D., Superintendent at New Hampshire Hospital, 105 Pleasant Street, Concord, New Hampshire 03301. Telephone (603) 271-2205.

LIAISON AND INPATIENT PSYCHIATRISTS WANTED

Bd. cert. or elig. required. Chillicothe VA Hospital is a 1000-bed hosp. with large aftercare program. JCAH approved. OSMA approved cont. med. ed. prog. for AMA Phy. Recognition Award. Hosp. located in southern Ohio natural recreation and scenic area, 45-min. from Columbus. Financial assistance in moving. Equal Employment Opportunity Employer. Write Chief of Staff, VA Hospital, Chillicothe, OH 45601 or call (614) 773-1141, ext. 202.

University of Pennsylvania
Department of Psychiatry
offers
FELLOWSHIPS
for
RESEARCH RESIDENTS
and
Post-Residency
PSYCHOPHARMACOLOGY TRAINING*



Fellowship positions are available for training in clinical and laboratory skills for psychiatric and psychopharmacological research with emphasis on individual participation in specific studies. Positions are available to individuals who have completed two or more years of residency training in psychiatry. The program offers participation in a broad range of ongoing studies as well as providing formal and informal study programs to provide in-depth exposure to relevant biochemical and pharmacological knowledge. Supervision is provided by senior staff members and fellows are aided and encouraged in planning research projects and the preparation of research grant applications and papers.

For further information, please write to:

J. Mendels, M.D.
Professor of Psychiatry
c/o Depression Research Unit
Veterans Administration Hospital
Philadelphia, Pennsylvania 19104

*Psychopharmacology Training Fellowships available only to U.S. citizens or permanent residents.

To get schizophrenic patients out of the hospital and to keep them out is one of psychiatry's principal goals today.
And we're doing something about it...
...with the benefits of a high potency agent. Rapidly effective in acute schizophrenia, with less total milligrams than with orally administered agents over the same period of time. Fewer autonomic side effects and less sedating than low potency agents. (There is, however, a higher incidence of largely manageable extrapyramidal reactions.)
...with a unique, reliable delivery system. A long-acting injectable neuroleptic that substantially reduces readmissions for outpatients, is often effective where oral medications fail in poor absorbers, can open up long-standing chronic schizophrenics to rehabilitative therapy.
...with economy of time and money. As maintenance therapy, Prolixin Decanoate provides important savings – both in medication administration time and in medication costs.
Prolixin Decanoate®
(Fluphenazine Decanoate Injection)
helping you reach your goals
See next page for brief summary.

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2%(w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia or liver damage, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

STAFF PSYCHIATRIST

This position is in an established 265 bed, JCAH accredited psychiatric facility, located in a university community of 30,000. Full time position includes providing training and supervision to psychologists, social workers, and nurses. Other duties include conducting patient evaluations, developing treatment plans, and evaluating and prescribing psychoactive medication. Salary open. Send resume with salary requirements to Personnel Director, P.O. Box 4008, Austin, Texas 78765.

DIRECTOR OF CLINICAL SERVICES

A challenging opportunity exists for a senior psychi within the Department of Health, Province of New B wick. As a member of the head office team for M Health Services, the successful applicant will supervis clinical program. The specific responsibility is to ensu effective clinical service through clinical evaluation cedures, consultation on complex cases, recruitment of psychiatrists, professional development of staff, prom of coordination between the various components of the tal health services system, contributing to program dev ment and evaluation activities, and fostering cooper with professional organizations.

Applicants are invited from specialists with a certific psychiatry of the Royal College of Physicians and Sur of Canada who have had extensive and progressively re sible experience in community mental health ser Competence in both Official Languages is desirable competence in English is essential.

An attractive salary and generous fringe benefit offered. Interested candidates should send a curric vitae or requests for information to:

J. A. Wolstenholme
Executive Director
Mental Health Service
Department of Health

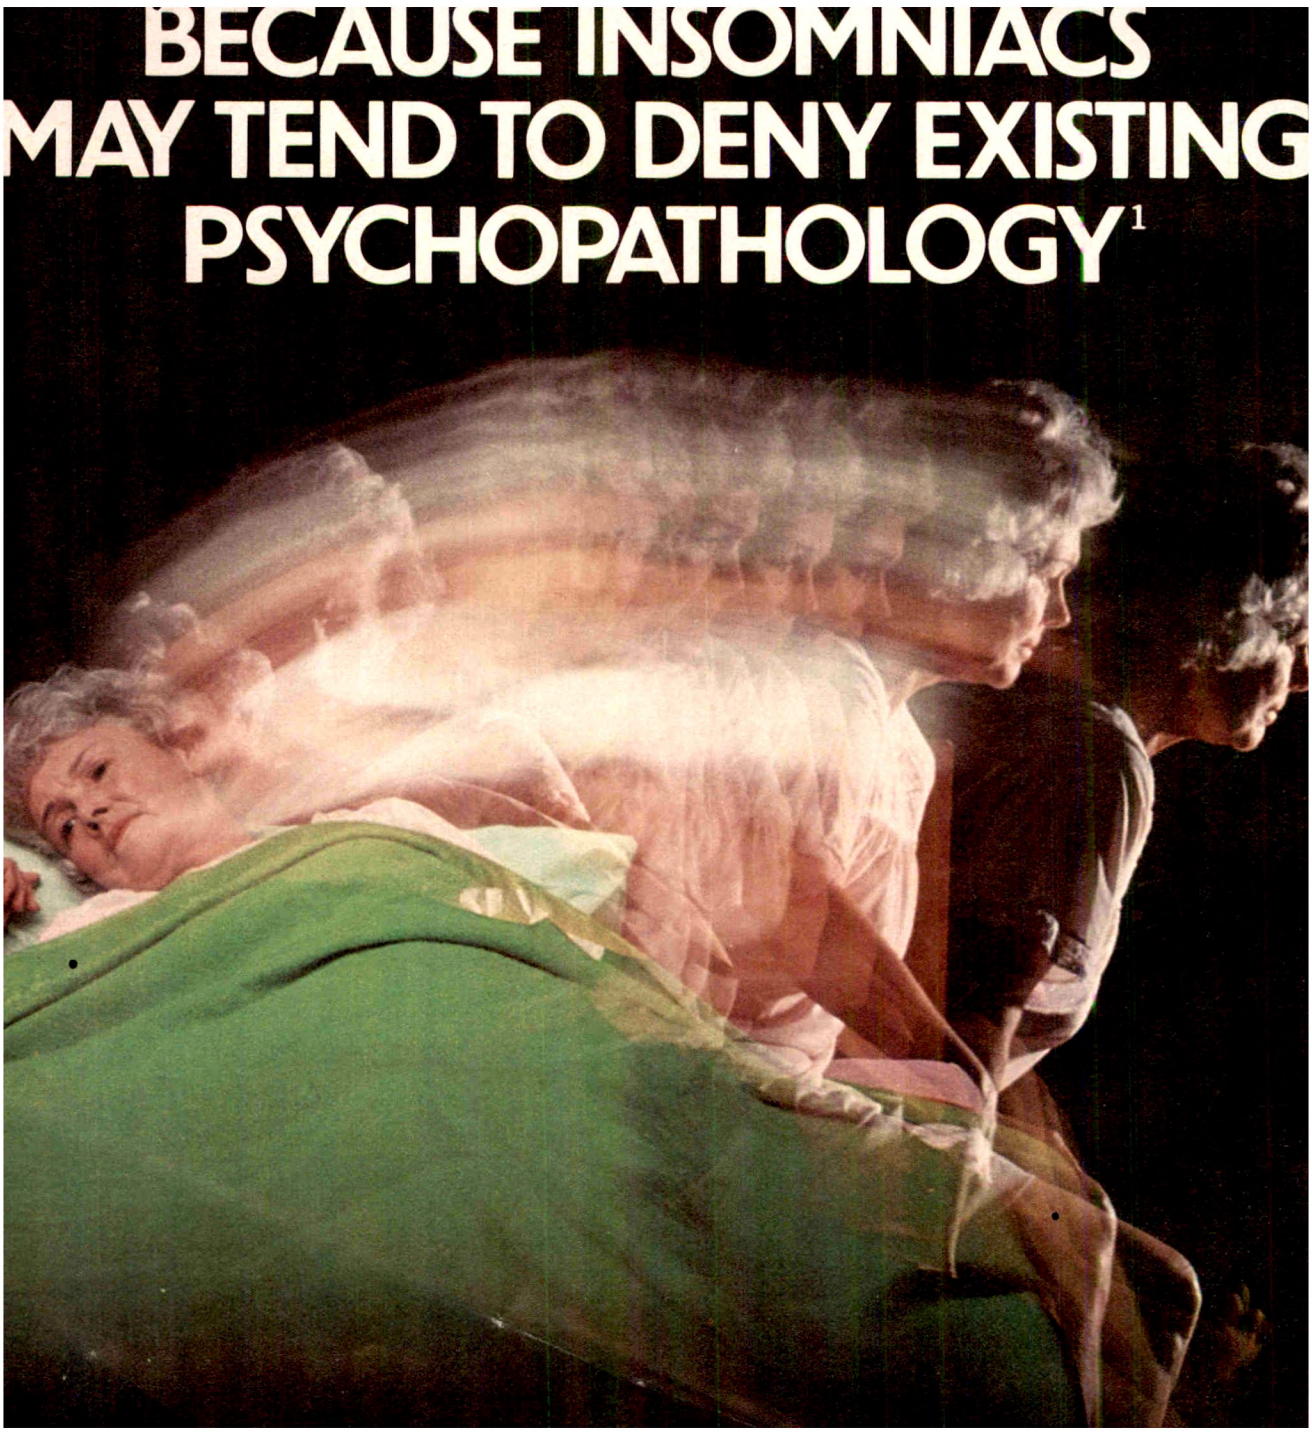
THE HEALTH SCIENCES CENTRE
and the
UNIVERSITY OF MANITOBA
invite applications for the position of
DIRECTOR OF CHILD AND ADOLESCENT PSYCHIATRY

H.S.C. positions are open equally to men and women.



The Health Sciences Centre is one of the continent's largest health care facilities with 1300 beds. The Centre is Manitoba's cipal referral institution for complex health problems and the province's major hospital for teaching and research. It is cen located in Winnipeg, Manitoba's largest city, with a population of 600,000 people, which is internationally known f cultural, sports and recreational activities.

The director shall be responsible for the development and co-ordination of Child and Adolescent Psychiatry programmes i dergraduate and graduate education and research, as well as the administration of service delivery systems.

This is a major academic position in a well established University Department of Psychiatry with an eclectic base, and str in the area of psychotherapy.

Other academic positions are also available in our Child Psychiatry Section.

Please direct enquiries to: Robert M. Martin, Ph.D.
Associate Head

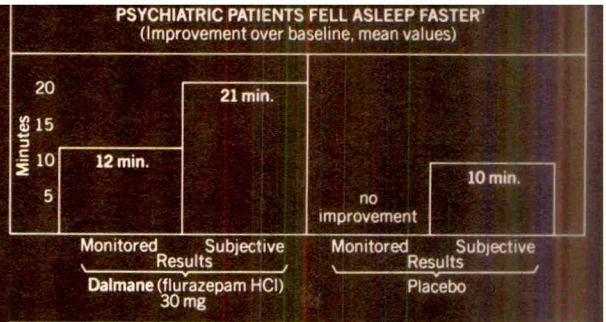
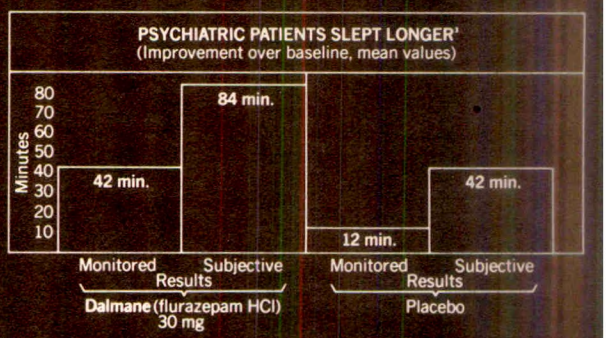
BECAUSE INSOMNIACS
MAY TEND TO DENY EXISTING
PSYCHOPATHOLOGY[1]

DALMANE®
(flurazepam HCl) C IV



30-MG AND 15-MG CAPSULES



for symptomatic relief of insomnia during psychotherapy

As you know, many insomniacs focus on somatic complaints rather than face the emotional problems that are the basis of their illness. When denial presents a block to effective therapy, pharmacologic intervention may be indicated. In such cases Dalmane, with sleep laboratory proof of efficacy, may prove especially useful as adjunctive treatment.[1]

proved effective for insomniac psychiatric patients[2,3]

In a placebo-controlled study, Dalmane 30 mg *h.s.*, administered for 7 nights to 49 hospitalized psychiatric patients, reduced the time required to fall asleep and increased the sleep duration time. These data, recorded by special monitors, agreed with subjective estimates made by patients on daily post-sleep questionnaires.

proved effective for 28 consecut nights in the sleep laboratory[4-6]

Dalmane (flurazepam HCl) is the only hypnotic proved effective for a 28-night period.[4-6] In sleep laboratory stud of chronic insomniacs, Dalmane has demonstrated a sig nificant reduction in the time required to fall asleep and in total wake time, during short-, intermediate- and longe term administration.[4] Where a hypnotic agent is needed for more than a few nights, Dalmane appears to be relatively safe as well as effective.[6] Although prolonged adm istration of Dalmane is seldom necessary, with repeated use periodic blood counts and liver and kidney function tests are recommended.

Please see following page for a summary of product information.

ROC

EFFECTIVE ADJUNCTIVE THERAPY IN PSYCHIATRIC PRACTICE

DALMANE®
(flurazepam HCl)

One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

- ☐ sleep within 17 minutes, on average, proved in sleep laboratory studies[3]
- ☐ sleep for an average of 7 to 8 hours proved in sleep laboratory studies[3]
- ☐ no need to repeat dose or increase dosage[2-6]

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).
Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**
Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated, limit initial dosage to 15 mg to preclude oversedation, dizziness and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect.
Adults: 30 mg usual dosage; 15 mg may suffice in some patients.
Elderly or debilitated patients: 15 mg initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Tranxene® (CLORAZEPATE DIPOTASSIUM) 4306CB

CAPSULES,
SINGLE DOSE TABLETS

Brief Summary

ACTIONS — Pharmacologically, clorazepate dipotassium has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine. (See CLINICAL PHARMACOLOGY section.)

INDICATIONS — TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS — TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS — TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS — In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS — The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION

For the symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For the symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg. TRANXENE initially, followed by 30 to 60 mg. in divided doses; 2nd 24 hours, 45 to 90 mg. in divided doses; 3rd 24 hours, 22.5 to 45 mg. in divided doses; 4th day, 15 to 30 mg. in divided doses. Thereafter gradually reduce to 7.5 to 15 mg. daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS — If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE — Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE (clorazepate dipotassium) as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY — Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption — Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED — TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 30 (NDC 0074-3418-30), 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:

TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 30 (NDC 0074-2699-30) and 100 (NDC 0074-2699-13).

8073256

Awake on the job,
yet anxiety controlled
Troublesome drowsiness uncommon. Tranxene lets you manage anxiety in most patients without problem sedation. Any initial drowsiness is usually transient. By avoiding excessive sedation, Tranxene helps you calm patients without compromising their capacities.*

THE AMERICAN JOURNAL OF PSYCHIATRY

In this issue

Psychiatry and the Fiscal Third Party

By Paul Chodoff

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

BACK HOME

THORAZINE®

brand of

CHLORPROMAZINE

Tablets:
50 and 100 mg
of the HCl

Home from the hospital. He went in with a psychiatric emergency but left more like himself—delusions, hallucinations, and other psychotic target symptoms under control with 'Thorazine'. And 'Thorazine' maintenance can help keep him out of the hospital in the future.

From initial psychiatric emergency through maintenance therapy, 'Thorazine' offers effective antipsychotic therapy with 18 convenient dosage forms and strengths. This means you can precisely tailor dosage to the individual patient's needs throughout the entire course of therapy.

'Thorazine'. The most widely tested and highly flexible antipsychotic available today.

Helps return psychotic patients to reality

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Therefore, avoid use in children or adolescents with suspected Reye's syndrome.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or obscure diagnosis of conditions such as intestinal obstruction, brain tumor, and Reye's syndrome (see Warnings). Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg. Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

MANIC ILLNESS

Baron Shopsin, editor

This volume surveys current clinical, pharmacological, and chemical information on mania. Leading experts review such topics as psychoanalytic aspects, epidemiology, risk factors, genetic aspects, differential diagnosis, neuropharmacological considerations, neuroendocrine function, psychopharmacotherapy, and electroseizure therapy.

340 pages, $18.00 (1978)

CONVULSIVE THERAPY: THEORY AND PRACTICE

Max Fink

This examination of electroconvulsive therapy discusses clinical and experimental data and presents guides for effective use. The findings of neurophysiologic (particularly EEG), psychologic, linguistic, biologic, biochemical, and pathologic studies of ECT are described, much of the data coming from the author's own extensive research.

380 pages, $24.00 (1978)

PSYCHOPHARMACOLOGY: A GENERATION OF PROGRESS

Sponsored by the American College of Neuropsychopharmacology (ACNP)

M. A. Lipton, A. DiMascio, and K. F. Killam, editors

". . . Splendidly edited and comprehensive great work. The volume must be regarded as an outstanding editorial achievement, neatly emphasizing the unity of research purpose in scores of tightly written, well documented papers. It is hard to imagine a professional with even a moderate interest in psychopharmacological research who will not want to have this volume at hand."—Behavioral Medicine

1760 pages, 7 x 10 inches, $49.50 (1978)

SENSORY PROCESSING, PERCEPTION, AND BEHAVIOR

R. B. Livingston

This monograph addresses itself to a central problem of human life, the problem of communication. It presents the main biological foundations for perception, judgment, and behavior, in an evolutionary and developmental context. In addition, it summarizes the evidence essential for understanding normal and abnormal subjective experience and behavior.

112 pages, softcover, $8.50 (1978)

DRIVES AND REINFORCEMENTS: Behavioral Studies of Hypothalamic Functions

James Olds

"Every neuroscience student should be exposed to this book. . . to learn how to study the brain on its own terms, by the integration of many kinds of information. "This simple and insightful book does three things. It demonstrates Olds's question-and-answer approach to brain research, it integrates the basic findings in neuroanatomy, neurochemistry, and electrophysiology that are related to brain reward systems, and it tries to point the way to a vein of research that would lead to a greater understanding of mental disease and drug abuse."—Science

148 pages, softcover, $9.00 (1977)

CRITICAL ISSUES IN PSYCHIATRIC DIAGNOSIS

American Psychopathological Association Series

R. L. Spitzer and D. F. Klein, editors

This volume addresses many important issues which have arisen in the course of re-evaluating the theory and practice of psychiatric diagnosis. Four important areas are discussed: Definition of Labeling and Mental Illness; The Role of Psychological Testing in Psychiatric Diagnosis; Genetics as a Tool in the Validation of Psychiatric Diagnosis; and Laboratory Approaches to Psychiatric Diagnosis.

360 pages, $25.00 (1978)

ANOREXIA NERVOSA

R. A. Vigersky, editor

This volume is the first comprehensive discussion of the many facets of anorexia nervosa, a disorder of unknown etiology. This review will be of particular interest to psychiatrists because of the psychologic and perceptual abnormalities associated with this disease.

408 pages, $19.50 (1977)

GILLES DE LA TOURETTE SYNDROME

A. K. Shapiro, E. S. Shapiro, R. D. Bruun, and R. D. Sweet

"This work is the definitive treatise on this syndrome. This book can be highly recommended, not only for study of Gilles de la Tourette's syndrome but also as an example of the modern techniques we have available to explore medical and neurological disorders."—JAMA

450 pages, $19.00 (1978)

THE PSYCHOLOGY OF PAIN

R. A. Sternbach, editor

The purpose of this book is to provide a systematic review of the literature on the psychology of pain, gathering into one convenient volume references scattered in a wide and diversified area. It will be valuable for psychiatrists, psychologists, neurologists, and anesthesiologists.

282 pages, $19.50 (1978)

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, and are not being considered for publication elsewhere. Papers with multiple authors are reviewed with the assumption that all authors have approved them.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. All submissions must be accompanied by a cover letter *signed by all authors* and using the following wording:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. The cover letter in such cases should contain the following wording and should be signed by all authors:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 2–3 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by the appropriate cover letter, including the copyright transfer statement, will not be reviewed until such a statement is received.

Authors will be notified as soon as possible of the receipt of their paper; at this time, the paper will be assigned a number that must be included in all further correspondence. It is imperative that authors of papers under consideration notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in *final form*, i.e., are ready for review. Authors must *not* submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions, and not all papers can be published in the *Journal*. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; this number must appear in any further communications about the paper. The copyright transfer statement described above must accompany annual meeting papers submitted for review.

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent, including references, tables, and figures (about 15 manuscript pages). Brief Communications—2,500 words or equivalent (about 10 manuscript pages). Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures can be used in this section). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 25 double-spaced pages (about 7,500 words) and should have no more than 100 references. All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures or references, etc. Single case reports will not be accepted as regular articles or Brief Communications; these papers should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and *no figures*) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular or Brief Communication length (a "prompt publication policy" is automatically in effect for Clinical and Research Reports). These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality, and authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed *double-spaced* throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review or listing may be sent directly to the Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Book reviews are usually solicited by the editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer. Reviews are usually less than 500 words long, seldom contain references, and will be edited.

TYPING AND ARRANGING THE PAPER

All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) *nonerasable* bond paper. All parts of the manuscript, including case reports, quotations, references, and tables, must be double-spaced throughout. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Please include degrees (other than honorary or undergraduate) after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. The authors' position titles and affiliations should be given in a paragraph using complete sentences. A full address is necessary only for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications (no précis is used in the Clinical and Research Reports section). The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material; a complete review of the literature is rarely desirable. *Accuracy of citation is the author's responsibility.* References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do *not* arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below and on the next page, double-spaced *throughout* (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26

2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information available in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit use for educational purposes or of an author who wishes to reprint his/her own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Reprint orders from others should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The November 1978 issue of

The American Journal of Psychiatry

will feature

- **Psychodynamics and Developmental Psychology of the Borderline Patient: A Review of the Literature**

  By Edward R. Shapiro

Hallucinations... delusions... thought disorders... controlled

Navane (thiothixene) rapidly controls hallucinations as well as the agitation and hostility patterns they frequently generate.

Rapid control of psychotic symptoms on admission

Navane provides effective, rapid control of the major symptoms of psychosis including hallucinations, delusions, agitation, hostility, and thought disorders.[1-5] Navane promotes rapid progress, usually without the over-sedation or cardiovascular problems that can impede the therapeutic course.

Continued long-term improvement

Because Navane provides long-term outpatient control of psychotic symptoms, it can enable many patients to function effectively at home and on the job and to adjust rapidly to the community.[6]

Effectiveness rarely compromised by adverse reactions

Navane allows patients to remain alert and active, seldom causing over-sedation or drowsiness.[7] Hypotension and other cardiovascular reactions[5,6,8] are seldom reported and the occurrence of unpleasant anticholinergic side effects such as dry mouth or constipation is rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled through dosage adjustments or antiparkinson agents.

Rapid control
Long-term improvement

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml. Intramuscular 2 mg./ml.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane* (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

THERAPEUTIC HYPNOSIS

A comprehensive text which critically examines the major historical, theoretical and clinical developments in the therapeutic use of hypnosis. With over twenty-five years of experience in the field of hypnotherapy, this esteemed authority presents the most current and effective methods in this expanding profession. Special attention is devoted to the successful utilization of hypnoaversion therapy in the treatment of individuals suffering from chronic alcoholism, nicotinism, obesity and other debilitating conditions. Also discussed are the clinical applications of hypnosis to a great variety of medical and psychological specialties.

PSYCHOPHARMACOLOGY AND PSYCHOTHERAPY: Synthesis or Antithesis?

Compiled by outstanding psychiatric clinicians and researchers in psychotherapy, psychopharmacology, and psychoanalysis, this important book comprehensively covers the major areas of psychopathology from the psychological and biological points of view. Topics are treated from both a theoretical and an applied perspective, and pertain to a wide range of issues including the treatment of schizophrenia and manic-depressive illness.

CALM
AND
ALERT*
THE
PATIENT ON
VERSTRAN®
(prazepam)
CIV

Smooth, consistent anxiolytic action is the reason.

Proven efficacy

- Effective symptomatic relief of anxiety, whether psychic or somatic in origin
- Therapeutic response achieved with first dose
- Verstran—a suitable antianxiety alternative to diazepam

Established safety

- Virtually no drowsiness* in most Verstran patients (less than 10%)
- Other side effects, if present, are minimal†
- Verstran is appropriate concomitant therapy in most somatic disorders‡
- No accumulation after steady state is reached

Dosage versatility

- The simplicity of a single-strength 10-mg scored tablet, for easy titration and improved patient compliance
- The flexibility of *once daily*§ dosage
- The option of a *b.i.d.* dosage regimen, gradually adjustable within a range of 20 to 60 mg/day

*As with all CNS-acting agents, patients should be cautioned against driving, drinking, or engaging in hazardous activities.

†Data on file, Warner/Chilcott Medical Department.

TO ENHANCE PATIENT RESPONSIVENESS CONSIDER

VERSTRAN (prazepam) Ⓥ

VERSTRAN® (prazepam) Ⓥ

Caution: Federal law prohibits dispensing without prescription.

Description: Verstran (prazepam), a benzodiazepine derivative, is identified chemically as 7-chloro-1-(cyclopropylmethyl)-1,3-dihydro-5-phenyl-2H-1,4-benzodiazepin-2-one. The molecular weight is 324.8 and the structural formula is as follows:

Clinical Pharmacology: Studies in normal subjects have shown that Verstran (prazepam) has depressant effects on the central nervous system. Oral administration of single doses as high as 60 mg and divided doses up to 100 mg t.i.d. (300 mg total daily dose) were without toxic effects.

Single oral doses of Verstran in normal subjects produced peak blood levels at 6 hours postadministration, with significant amounts still present after 48 hours. Verstran was slowly absorbed over a prolonged period, rather constant blood levels were maintained, and excretion was prolonged. The mean half-life of prazepam measured in subjects given 10 mg t.i.d. for one week was 63 (±15 s.d.) hours before and 70 (±10 s.d.) hours after multiple dosing — a nonsignificant difference. Human metabolism studies showed that prior to elimination from the body, prazepam is metabolized in large part to 3-hydroxyprazepam and oxazepam.

Indications: Verstran (prazepam) is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

The effectiveness of Verstran (prazepam) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

Contraindications: Verstran (prazepam) is contraindicated in patients with a known sensitivity to the drug and in those with acute narrow angle glaucoma.

Warnings: Verstran (prazepam) is not recommended in psychotic states and in those psychiatric disorders in which anxiety is not a prominent feature.

Patients taking Verstran should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery, including motor vehicles.

Because Verstran has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, including phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The effects of alcohol may also be increased.

Physical and Psychological Dependence: Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepine drugs. These symptoms include convulsions, tremor, abdominal and muscle cramps, vomiting and sweating. Addiction-prone individuals, such as drug addicts and alcoholics, should be under careful surveillance when receiving benzodiazepines because of the predisposition of such patients to habituation and dependence.

Precautions:

Use in Pregnancy and Lactation:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Verstran (prazepam) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug. In view of their molecular size, Verstran and its metabolites are probably excreted in human milk. Therefore, this drug should not be given to nursing mothers.

In those patients in whom a degree of depression accompanies the anxiety, suicidal tendencies may be present, and protective measures may be required. The least amount of drug that is feasible should be available to the patient at any one time.

Patients taking Verstran for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed. Hepatomegaly and cholestasis were observed in chronic toxicity studies in rats and dogs.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

Pediatric Use: Safety and effectiveness in patients below the age of 18 have not been established.

Adverse Reactions: The side effects most frequently reported during double-blind placebo-controlled trials employing a typical 30 mg divided total daily dose and the percent incidence in the Verstran (prazepam) group were: fatigue (11.6%), dizziness (8.7%), weakness (7.7%), drowsiness (6.8%), lightheadedness (6.8%), and ataxia (5.0%). Less frequently reported were: headache, confusion, tremor, vivid dreams, slurred speech, palpitation, stimulation, dry mouth, diaphoresis, and various gastrointestinal complaints. Other side effects included: pruritus, transient skin rashes, swelling of feet, joint pains, various genitourinary complaints, blurred vision, and syncope. Single nightly dose, controlled trials of variable dosages showed a dose-related incidence of these same side effects. Transient and reversible aberrations of liver function tests have been reported, as have slight decreases in blood pressure and increases in body weight.

These findings are characteristic of benzodiazepine drugs.

Overdosage: As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

If vomiting has not occurred spontaneously, it should be induced. Immediate gastric lavage is also recommended. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though unlikely, may be controlled with Levophed® (levarterenol bitartrate) or Aramine® (metaraminol bitartrate). Caffeine and Sodium Benzoate Injection, USP, may be used to counteract central nervous system depressant effects.

Dosage and Administration: Verstran (prazepam) is administered orally in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 20 to 60 mg daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a divided daily dose of 10 mg to 15 mg. (See Precautions.)

Prazepam may also be administered as a single dose daily at bedtime. The recommended starting nightly dose is 20 mg. The response of the patient to several days' treatment will permit the physician to adjust the dose upward or, occasionally, downward to maximize antianxiety effect with a minimum of daytime drowsiness. The optimum dosage will usually range from 20 to 40 mg.

Drug Interactions: If Verstran (prazepam) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If Verstran is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

How Supplied: Verstran (prazepam) 10 mg light blue, scored tablets in bottles of 100 (N 0047-0276-51) and 1000 (N 0047-0276-60).

STORE BETWEEN 59°–86° F (15°–30° C).

Deal effectively with behavioral disorientation in general hospital populations... here's how:

A New Book!
MASSACHUSETTS GENERAL HOSPITAL HANDBOOK OF GENERAL HOSPITAL PSYCHIATRY

Increase your understanding of the psychiatric symptoms that can — and often do — erupt in the physically-ill. This long-awaited book thoroughly examines the behavioral disorientation resulting from hospitalization and analyzes the psychiatrist's role on the health team. Noted authorities focus on both chronic and acute illnesses — chronic pain, accidents, spinal cord injuries, burns and renal disorders — and offer valuable suggestions you can use to prevent or alleviate trauma. You'll be especially interested in a unique chapter "Psychiatric Consultation for Treatment Decisions in Irreversible Illness". It not only discusses the ethical aspects of decision-making and judging responsibility, but outlines a protocol for formulating difficult decisions as well. Be among the first to benefit from the valuable insights in this innovative volume — order your copy today!

Edited by Thomas P. Hackett, M.D. and Ned H. Cassem, M.D.; with 19 contributors. November, 1978. Approx. 512 pages, 13 illustrations. About $14.95.

Precise, easy-to-use
The B24 III SERIES
Electroconvulsive
THERAPY INSTRUMENTS

Designed to provide the physician with the ultimate in precision dosage, with consistency of output assured by the following:

- *Line Voltage Compensation*—Automatically adjusts variations in line voltage.
- *Pre-programmed Voltage Selection*—Offers a choice of 11 voltage levels, from 70 to 170 volts.
- *Automatic Treatment Timing*—Will adjust from 0.1 second to 1.0 second, with or without Glissando
- *Current Output Indicators*—During treatment current flow is clearly indicated.

Exclusive Patient Test Module allows a complete systems integrity check prior to treatment. 100% solid state circuitry assures clinical accuracy and dependability.

The B24 III series meets all requirements for Underwriters Laboratories—UL 544, Standards for Medical and Dental Equipment.

In depression...

3 of 10 patients will fail to respond to initial therapy.

make

PERTOFRANE® (desipramine HCl NF)

your first choice for the 3 of 10 patients who don't respond.

because of:

- **CLINICAL EFFECTIVENESS** even when "most patients had a history of several depressive episodes, hospitalizations, ECT or poor response to numerous other drugs."[1]

- **LOW SIDE EFFECTS PROFILE** with less sedating properties than amitriptyline or doxepin[2] and less anticholinergic activity.[3]

- **ENHANCED PATIENT ACCEPTANCE** through a flexible dosage schedule plus rapid onset of action.

PERTOFRANE® when they don't respond.
(desipramine HCl NF)

USV LABORATORIES
USV Laboratories Inc.
Manati, P.R. 00701

Please see next page for brief summary of prescribing information and references.

PERTOFRANE®
(desipramine HCl NF)

Indication: For relief of mental depression. **Contraindications:** Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane (desipramine HCl) in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. The potentiation resulting from excessive use of alcohol may increase the danger inherent in a suicide attempt or overdosage. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine. **Dosage:** All patients except geriatric and adolescent: 75 to 150 mg./day in divided doses or as single daily dose. Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Therapy may be given in divided doses or as a single daily dose. **How Supplied:** 25 mg. capsules (pink), bottles of 100 and 1000. Also, 50 mg. capsules (maroon and pink), bottles of 100 and 1000.

PLAN AHEAD!!!
Order your 1979 Appointment Book Now !!!

The "week-at-a-glance" Appointment Book, published by the American Psychiatric Association, has been developed over several years to satisfy the needs of as many members as possible. It contains a comprehensive list of addresses and annual meeting dates of all major organizations and agencies of interest to psychiatrists. Members who have not tried this book in the past are urged to do so. It is returnable within 30 days for a full refund if not acceptable. In addition, the name of the physician or hospital can be imprinted on the front cover for $1.00 a copy, providing that the order is received by July 15.

The Pocket Size Appointment Book is also available and can be ordered in combination with the Desk Appointment Book.

Copies will be available September 1978

DESK: $10.00
POCKET: $6.00
BOTH: $15.00
10% Discount for 10-99 copies
15% Discount for 100 copies or more

While designed primarily for neurologists, child neurologists and neurosurgeons, consideration of recent advances and pertinent basic material will make the presentations useful to internists, psychiatrists, pediatricians and generalists.

Daily sessions, Monday through Friday, 9:00 am-12:20 pm; & 2:00-5:00 pm. Most of the 10 half-day sessions will treat a discrete topic from several points of view. The last day will be devoted entirely to child neurology.

ADULT NEUROLOGY: Neuro-oto-ophthalmology; Neurologic Manifestations of Internal Medical Diseases; CNS Malignancies; Headache — EEG; Epilepsy; Neuro-Radiology; Peripheral Neuropathies and Cerebrovascular Disease.

PEDIATRIC NEUROLOGY: CNS Degenerative Disease in Infancy; Ataxia in Childhood; Dysraphic Syndromes; Advances in Neonatal Neurology; Clinical Presentation of Myotonic Dystrophy in Childhood; and Cerebrovascular Disease in Childhood.

ADULT NEUROLOGY — 24 hrs Category 1 — PEDIATRIC NEUROLOGY — 6 hrs Category 1
COMBINED COURSE — 30 hrs, Category 1

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

THE BROWN SCHOOLS

An equal opportunity employer. All our programs are accredited by the appropriate Councils of the Joint Commission on Accreditation of Hospitals.

FJ:97:34

They thought Ed Sloan was just tired...

maybe he had narcolepsy

A narcoleptic can fall asleep almost anywhere, anytime. The results can be at least embarrassing...at most devastating.

Narcolepsy is often unrecognized

As a primary sleep abnormality narcolepsy is characterized by sleepiness, inappropriate sleep episodes, and cataplexy (episodes of muscular weakness precipitated by strong emotion). These are often accompanied by hypnagogic hallucinations, automatic behavior and/or disturbed nocturnal sleep. Sleep apnea may be a severe life-threatening complication of narcolepsy.

Besides its medical implications, narcolepsy may have drastic social consequences.

"All too often, the patient with disabling hypersomnolence is ignored by physicians for years and even decades, with the consequent tragic toll on his ability to learn and to work."[1]

Ritalin can help in narcolepsy

For narcoleptic sleepiness and sleep episodes, the cited authorities[1,2] most frequently use Ritalin (methylphenidate).

Ritalin® C II
(methylphenidate)

For the 200,000 narcoleptics who can't stay awake

Please turn page for brief prescribing information.

CIBA

Ritalin® C II
(methylphenidate)

For the 200,000 narcoleptics who can't stay awake

Ritalin® hydrochloride C II
(methylphenidate hydrochloride USP)
TABLETS

INDICATION
Narcolepsy.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.

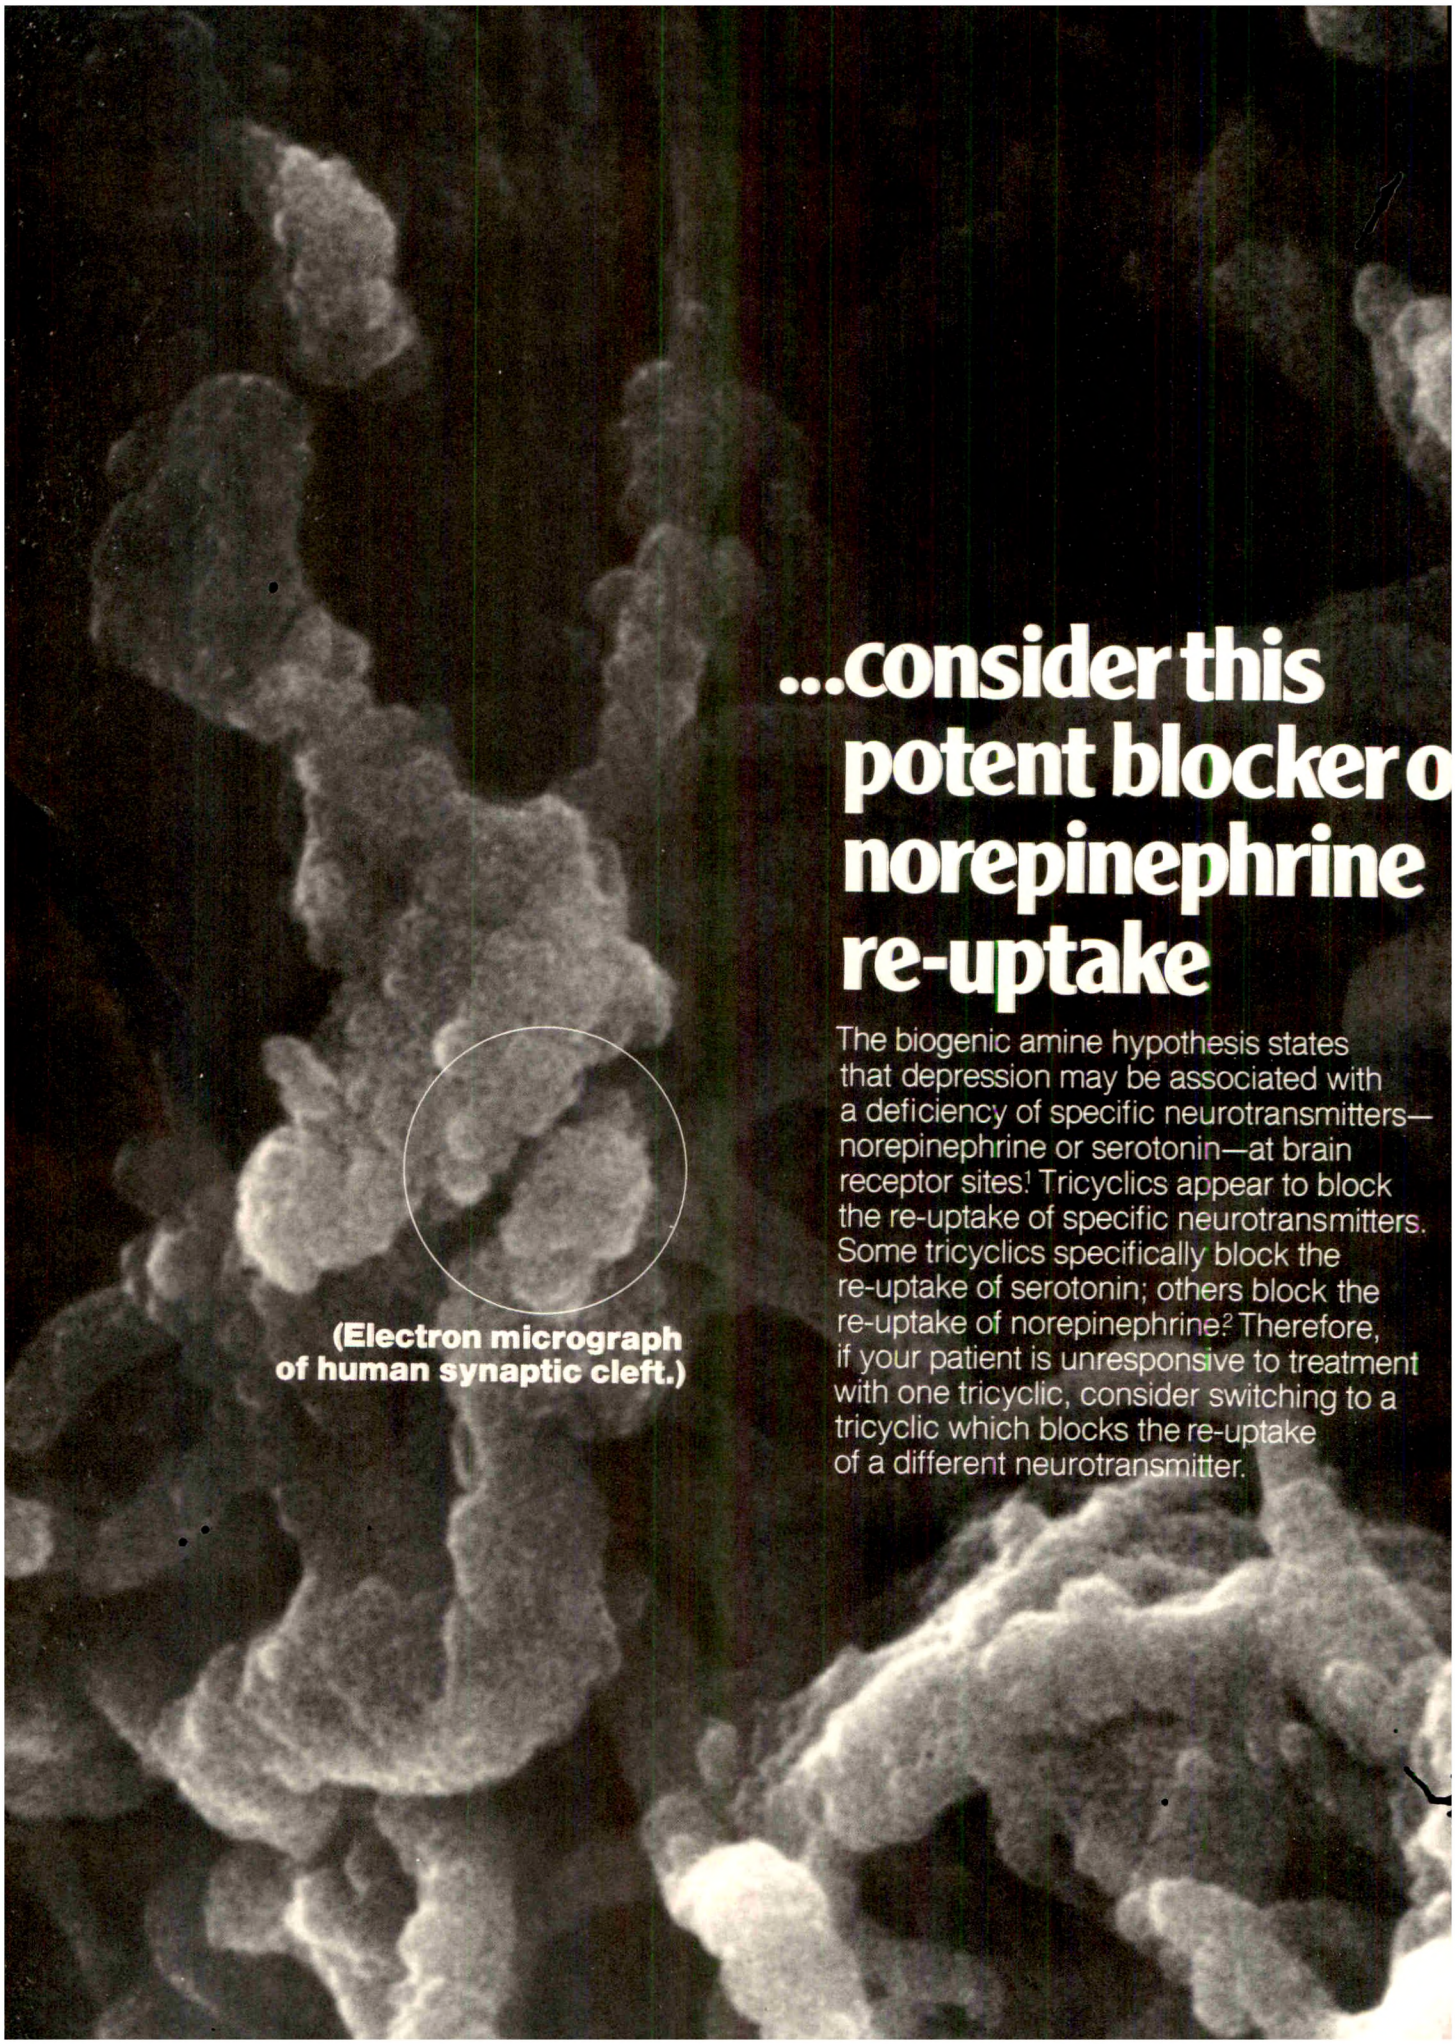
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.

C76-16 (Rev. 7/76) 665381



Consult complete product literature before prescribing.

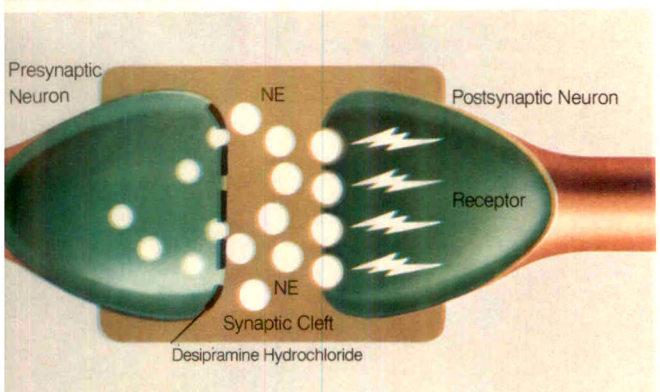
CIBA

When your patient is clinically depressed...
"...everything I saw was negative."

...consider this potent blocker o norepinephrine re-uptake



The biogenic amine hypothesis states that depression may be associated with a deficiency of specific neurotransmitters—norepinephrine or serotonin—at brain receptor sites.[1] Tricyclics appear to block the re-uptake of specific neurotransmitters. Some tricyclics specifically block the re-uptake of serotonin; others block the re-uptake of norepinephrine.[2] Therefore, if your patient is unresponsive to treatment with one tricyclic, consider switching to a tricyclic which blocks the re-uptake of a different neurotransmitter.

(Electron micrograph of human synaptic cleft.)

Norpramin®
(desipramine hydrochloride tablets NF)
25, 50, 75, 100, 150 mg.

Potent blocker of norepinephrine re-uptake

According to current theory[1,3] some tricyclic antidepressants may fail in certain types of depression because they are not sufficiently potent blockers of norepinephrine re-uptake. Laboratory studies have shown that desipramine is the most potent inhibitor of norepinephrine re-uptake.[4] Norpramin may work in some patients when other tricyclic antidepressants do not.

Consider it now, consider it next.

Less anticholinergic activity

(See Warnings section.)

Studies in animals[5] and in normal human subjects[6,7] have shown that desipramine has significantly less anticholinergic activity than amitriptyline or doxepin. The single bond side chain is associated with lower anticholinergic activity than these other leading antidepressants. This may mean:

- less dry mouth
- less blurred vision
- less urinary retention

Helps patients remain calm but active

Norpramin does not usually inhibit normal activity although patients should be cautioned as to driving or operating machinery if drowsiness occurs.

In addition...

Begins to improve sleep patterns within one week in some patients[8]

- Norpramin helps relieve the sleep disturbances that often accompany depression.
- As the depression is relieved, the difficulty in falling asleep, restlessness, and early morning awakening diminish.

Merrell

Now 300 mg. dosage range broadens clinical flexibility

A maximum dosage of 300 mg. a day, as a single or divided dose, may now be prescribed fo Norpramin. Since inadequate dosage is thought to be one of the major causes of treatment failure, the new therapeutic range should prove clinically helpful. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Norpramin®
(desipramine hydrochloride tablets NF)

AVAILABLE ONLY ON PRESCRIPTION

Brief Summary

MECHANISM OF ACTION: Available evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters such as norepinephrine and serotonin. Norepinephrine deficiency may be associated with relatively low urinary 3-methoxy-4-hydroxyphenyl glycol (MHPG) levels, while serotonin deficiencies may be associated with low spinal fluid levels of 5-hydroxyindolacetic acid.

While the precise mechanism of action of the tricyclic antidepressants is unknown, a leading theory suggests that they restore normal levels of neurotransmitters by blocking the re-uptake of these substances from the synapse in the central nervous system.

Evidence indicates that the secondary amine tricyclic antidepressants, including Norpramin, may have greater activity in blocking the re-uptake of norepinephrine. Tertiary amine tricyclic antidepressants, such as amitriptyline, may have greater effect on serotonin re-uptake.

Norpramin (desipramine hydrochloride) is not a monoamine oxidase (MAO) inhibitor and does not act primarily as a central nervous system stimulant. It has been found in some studies to have a more rapid onset of action than imipramine. Earliest therapeutic effects may occasionally be seen in 2 to 5 days, but full treatment benefit usually requires 2 to 3 weeks to obtain.

INDICATIONS: Norpramin (desipramine hydrochloride) is indicated for relief of symptoms in various depressive syndromes, especially endogenous depression.

CONTRAINDICATIONS: Desipramine hydrochloride should not be given in conjunction with, or within 2 weeks of, treatment with an MAO inhibitor drug; hyperpyretic crises, severe convulsions, and death have occurred in patients taking MAO inhibitors and tricyclic antidepressants. When Norpramin (desipramine hydrochloride) is substituted for an MAO inhibitor, at least 2 weeks should elapse between treatments. Norpramin should then be started cautiously and should be increased gradually.

The drug is contraindicated in the acute recovery period following myocardial infarction. It should not be used in those who have shown prior hypersensitivity to the drug. Cross sensitivity between this and other dibenzazepines is a possibility.

WARNINGS: **1.** Extreme caution should be used when this drug is given in the following situations: a. In patients with cardiovascular disease, because of the possibility of conduction defects, arrhythmias, tachycardias, strokes, and acute myocardial infarction. b. In patients with a history of urinary retention or glaucoma, because of the anticholinergic properties of the drug. c. In patients with thyroid disease or those taking thyroid medication, because of the possibility of cardiovascular toxicity, including arrhythmias. d. In patients with a history of seizure disorder, because this drug has been shown to lower the seizure threshold. **2.** This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. **3.** USE IN PREGNANCY: Safe use of desipramine hydrochloride during pregnancy and lactation has not been established; therefore, if it is to be given to pregnant patients, nursing mothers, or women of childbearing potential, the possible benefits must be weighed against the possible hazards to mother and child. Animal reproductive studies have been inconclusive. **4.** USE IN CHILDREN: Norpramin (desipramine hydrochloride) is not recommended for use in children since safety and effectiveness in the pediatric age group have not been established. **5.** The patient should be cautioned that this drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. **6.** In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage. **PRECAUTIONS:** **1.** It is important that this drug be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with this class of drug. Ordinary prudence requires that children not have access to this drug or to potent drugs of any kind; if possible this drug should be dispensed in containers with child-resistant safety closures. Storage of this drug in the home must be supervised responsibly. **2.** If serious adverse effects occur, dosage should be reduced or treatment should be altered. **3.** Norpramin (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates. **4.** The drug may cause exacerbation of psychosis in schizophrenic patients. **5.** Close supervision and careful adjustment of dosage are required when this drug is given concomitantly with anticholinergic or sympathomimetic drugs. **6.** Patients should be warned that while taking this drug their response to alcoholic beverages may be exaggerated. **7.** Clinical experience in the concurrent administration of ECT and antidepressant drugs is limited. Thus, if such treatment is essential, the possibility of increased risk relative to benefits should be considered. **8.** The sedative effects of Norpramin and benzodiazepines (*e.g.*, chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. **9.** This drug should be discontinued as soon as possible prior to elective surgery because of the possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients taking desipramine hydrochloride. **10.** Both elevation and lowering of blood sugar levels have been reported. **11.** Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

ADVERSE REACTIONS: Note: Included in the following listing are a few adverse reactions that have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when Norpramin (desipramine hydrochloride) is given.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic: numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus.

Anticholinergic: dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis, increased intraocular pressure; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs.

Hematologic: bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue.

Endocrine: gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

DOSAGE AND ADMINISTRATION: Not recommended for use in children. Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients compared to hospitalized patients, who are closely supervised. Dosage should be initiated at a low level and increased according to clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a period of time and should be at the lowest dose that will maintain remission.

Usual Adult Dose: The usual adult dose is 100 to 200 mg. per day. In more severely ill patients, dosage may be further increased gradually to 300 mg./day if necessary. Dosages above 300 mg./day are not recommended.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response.

Treatment of patients requiring as much as 300 mg. should generally be initiated in hospitals, where regular visits by the physician, skilled nursing care, and frequent electrocardiograms (ECG's) are available.

The best available evidence of impending toxicity from very high doses of Norpramin is prolongation of the QRS or QT intervals on the ECG. Prolongation of the PR interval is also significant, but less closely correlated with plasma levels. Clinical symptoms of intolerance, especially drowsiness, dizziness, and postural hypotension, should also alert the physician to the need for reduction in dosage. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

Adolescent and Geriatric Dose: The usual adolescent and geriatric dose is 25 to 100 mg. daily.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response to a usual maximum of 100 mg. daily. In more severely ill patients, dosage may be further increased to 150 mg./day. Doses above 150 mg./day are not recommended in these age groups.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

OVERDOSAGE: See prescribing information for a discussion of symptoms and treatment of overdose.

PKSAP-III

PSYCHIATRIC KNOWLEDGE AND SKILLS SELF-ASSESSMENT PROGRAM

CONTINUOUS OFFERING

PKSAP-III is again available. The Program, initially available to physicians in Spring/Summer, 1977, will differ in that central scoring services will not be provided. Each registrant will receive the question booklets, the Reference guidebook containing the correct answers and bibliography, a score worksheet, and the Performance Data Report, which will facilitate self-scoring, follow-up reading and study at the participant's convenience. For further program details, the Bulletin of Information, is available upon request to the APA, Office of Education.

To register, remit the appropriate fee with this application form to the APA, PUBLICATIONS SALES. PLEASE MAKE CHECKS PAYABLE TO APA, PKSAP-III.

FLEXIBLE DOSAGE TO MEET THE INTENSITY OF ANXIETY

□ for clinically manifest neurotic or psychoneurotic anxiety, and anxiety associated with somatic disease†

Approximate Milligram Equivalency*

AZENE ™ Clorazepate monopotassium	Diazepam	Chlordi-azepoxide	Oxazepam
3.25 mg	2 mg	5 mg	10 mg
6.5 mg	5 mg	10 mg	15 mg
13.0 mg	10 mg	25 mg	30 mg

*Based upon available information from manufacturers' package inserts.

□ an acceptable sedative profile

Drowsiness may occur at initiation of treatment, and with dosage increments.

Brief Summary of Prescribing Information

CONTRAINDICATIONS AZENE™ (clorazepate monopotassium) is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

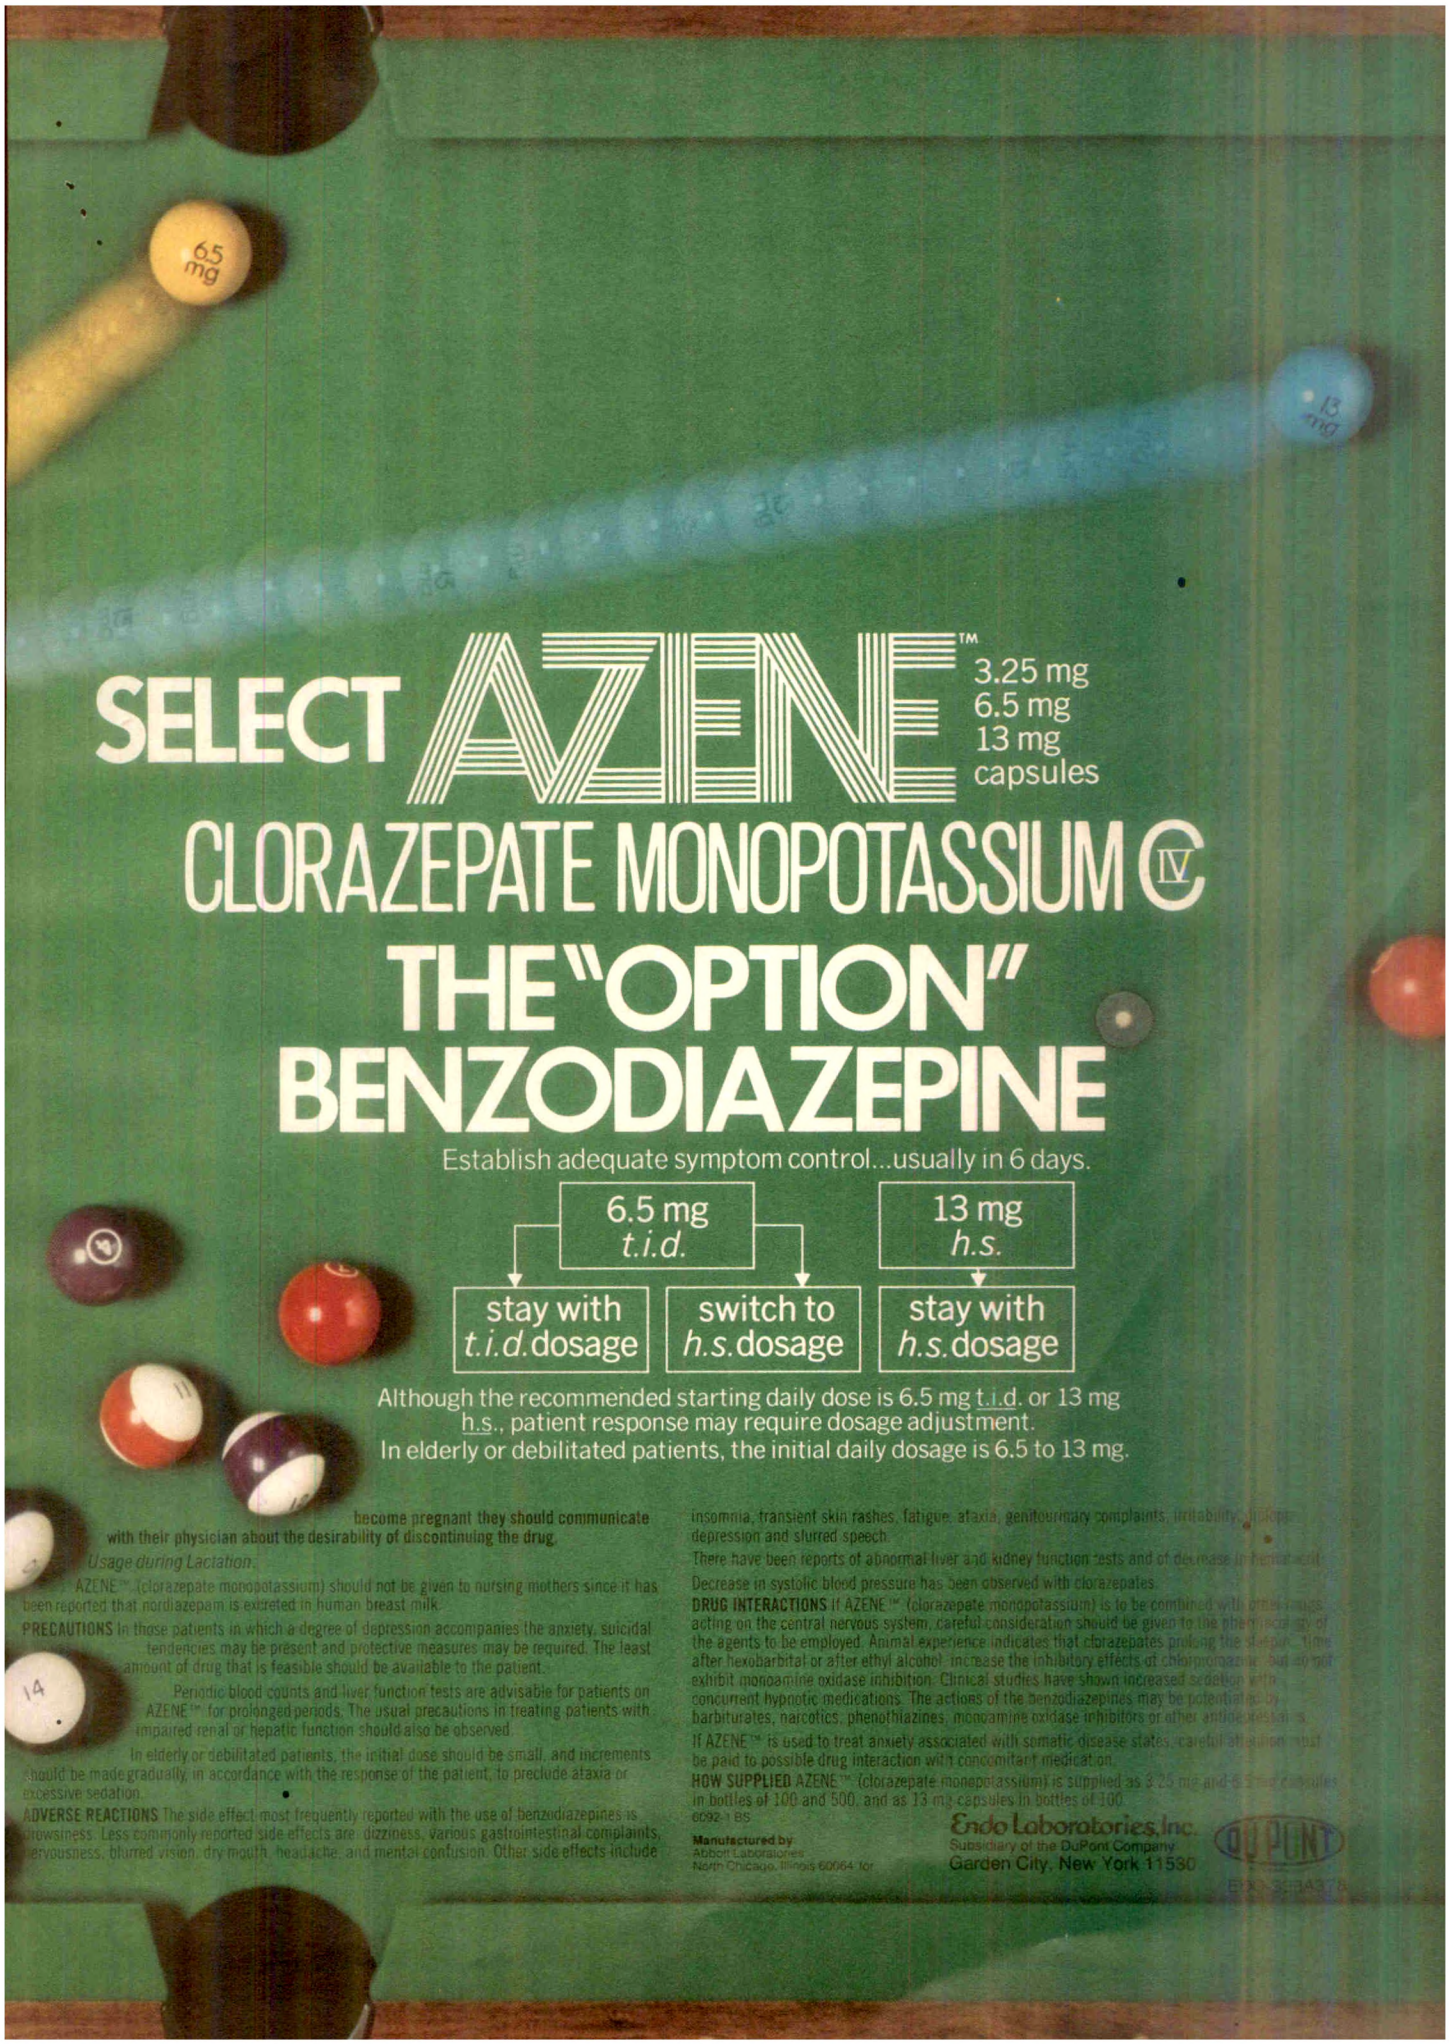
WARNINGS AZENE™ is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on AZENE™ should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since AZENE™ (clorazepate monopotassium) has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, AZENE™ is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.



Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Tolerance developed within 3 to 9 days in dogs. Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. AZENE™ (clorazepate monopotassium), a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to

†The effectiveness of AZENE™ in long-term use, that is, more than four months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

capsules

CLORAZEPATE MONOPOTASSIUM C IV

THE "OPTION" BENZODIAZEPINE

Establish adequate symptom control...usually in 6 days.

6.5 mg *t.i.d.*

- stay with *t.i.d.* dosage
- switch to *h.s.* dosage

13 mg *h.s.*

- stay with *h.s.* dosage

Although the recommended starting daily dose is 6.5 mg t.i.d. or 13 mg h.s., patient response may require dosage adjustment.
In elderly or debilitated patients, the initial daily dosage is 6.5 to 13 mg.

become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation.

AZENE™ (clorazepate monopotassium) should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Periodic blood counts and liver function tests are advisable for patients on AZENE™ for prolonged periods. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS The side effect most frequently reported with the use of benzodiazepines is drowsiness. Less commonly reported side effects are: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, initial depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed with clorazepates.

DRUG INTERACTIONS If AZENE™ (clorazepate monopotassium) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that clorazepates prolong the sleep time after hexobarbital or ethyl alcohol, increase the inhibitory effects of chlorpromazine, but do not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If AZENE™ is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

HOW SUPPLIED AZENE™ (clorazepate monopotassium) is supplied as 3.25 mg and 6.5 mg capsules in bottles of 100 and 500, and as 13 mg capsules in bottles of 100.

The easiest way
multiply and divide

Adds better dosage control

(+) Long term treatment of depression with amitriptyline requires careful dosage titration to meet the individual needs of each patient. Because all six strengths of Endep (amitriptyline HCl) are scored, you can easily change the dose by half-tablet steps, without waiting for the patient to fill a new prescription.

to add, subtract, amitriptyline...

Subtracts some of the drawbacks of antidepressant therapy

(−) Scored Endep (amitriptyline HCl) tablets may eliminate the need for a new prescription each time the dosage needs to be changed, saving time for you and money for your patient. And, by keeping the patient on the same strength tablet, there's less chance he'll become confused, as he might if changed to another size or color of amitriptyline.

Multiplies therapeutic options

(×) The pharmacokinetic properties of Endep (amitriptyline HCl) are such that its clinical effect is the same whether prescribed *t.i.d.* or as a single daily dose. Thus, once you have established the proper dosage, you can prescribe the entire dose *h.s.*, minimizing anticholinergic and sedative side effects and helping to assure patient compliance with this simple regimen.

By prescribing the higher strength tablets *h.s.*—secure in the knowledge that the dosage can be adjusted in half-tablet steps without resorting to a new prescription—your patient will economize further on a per milligram basis.

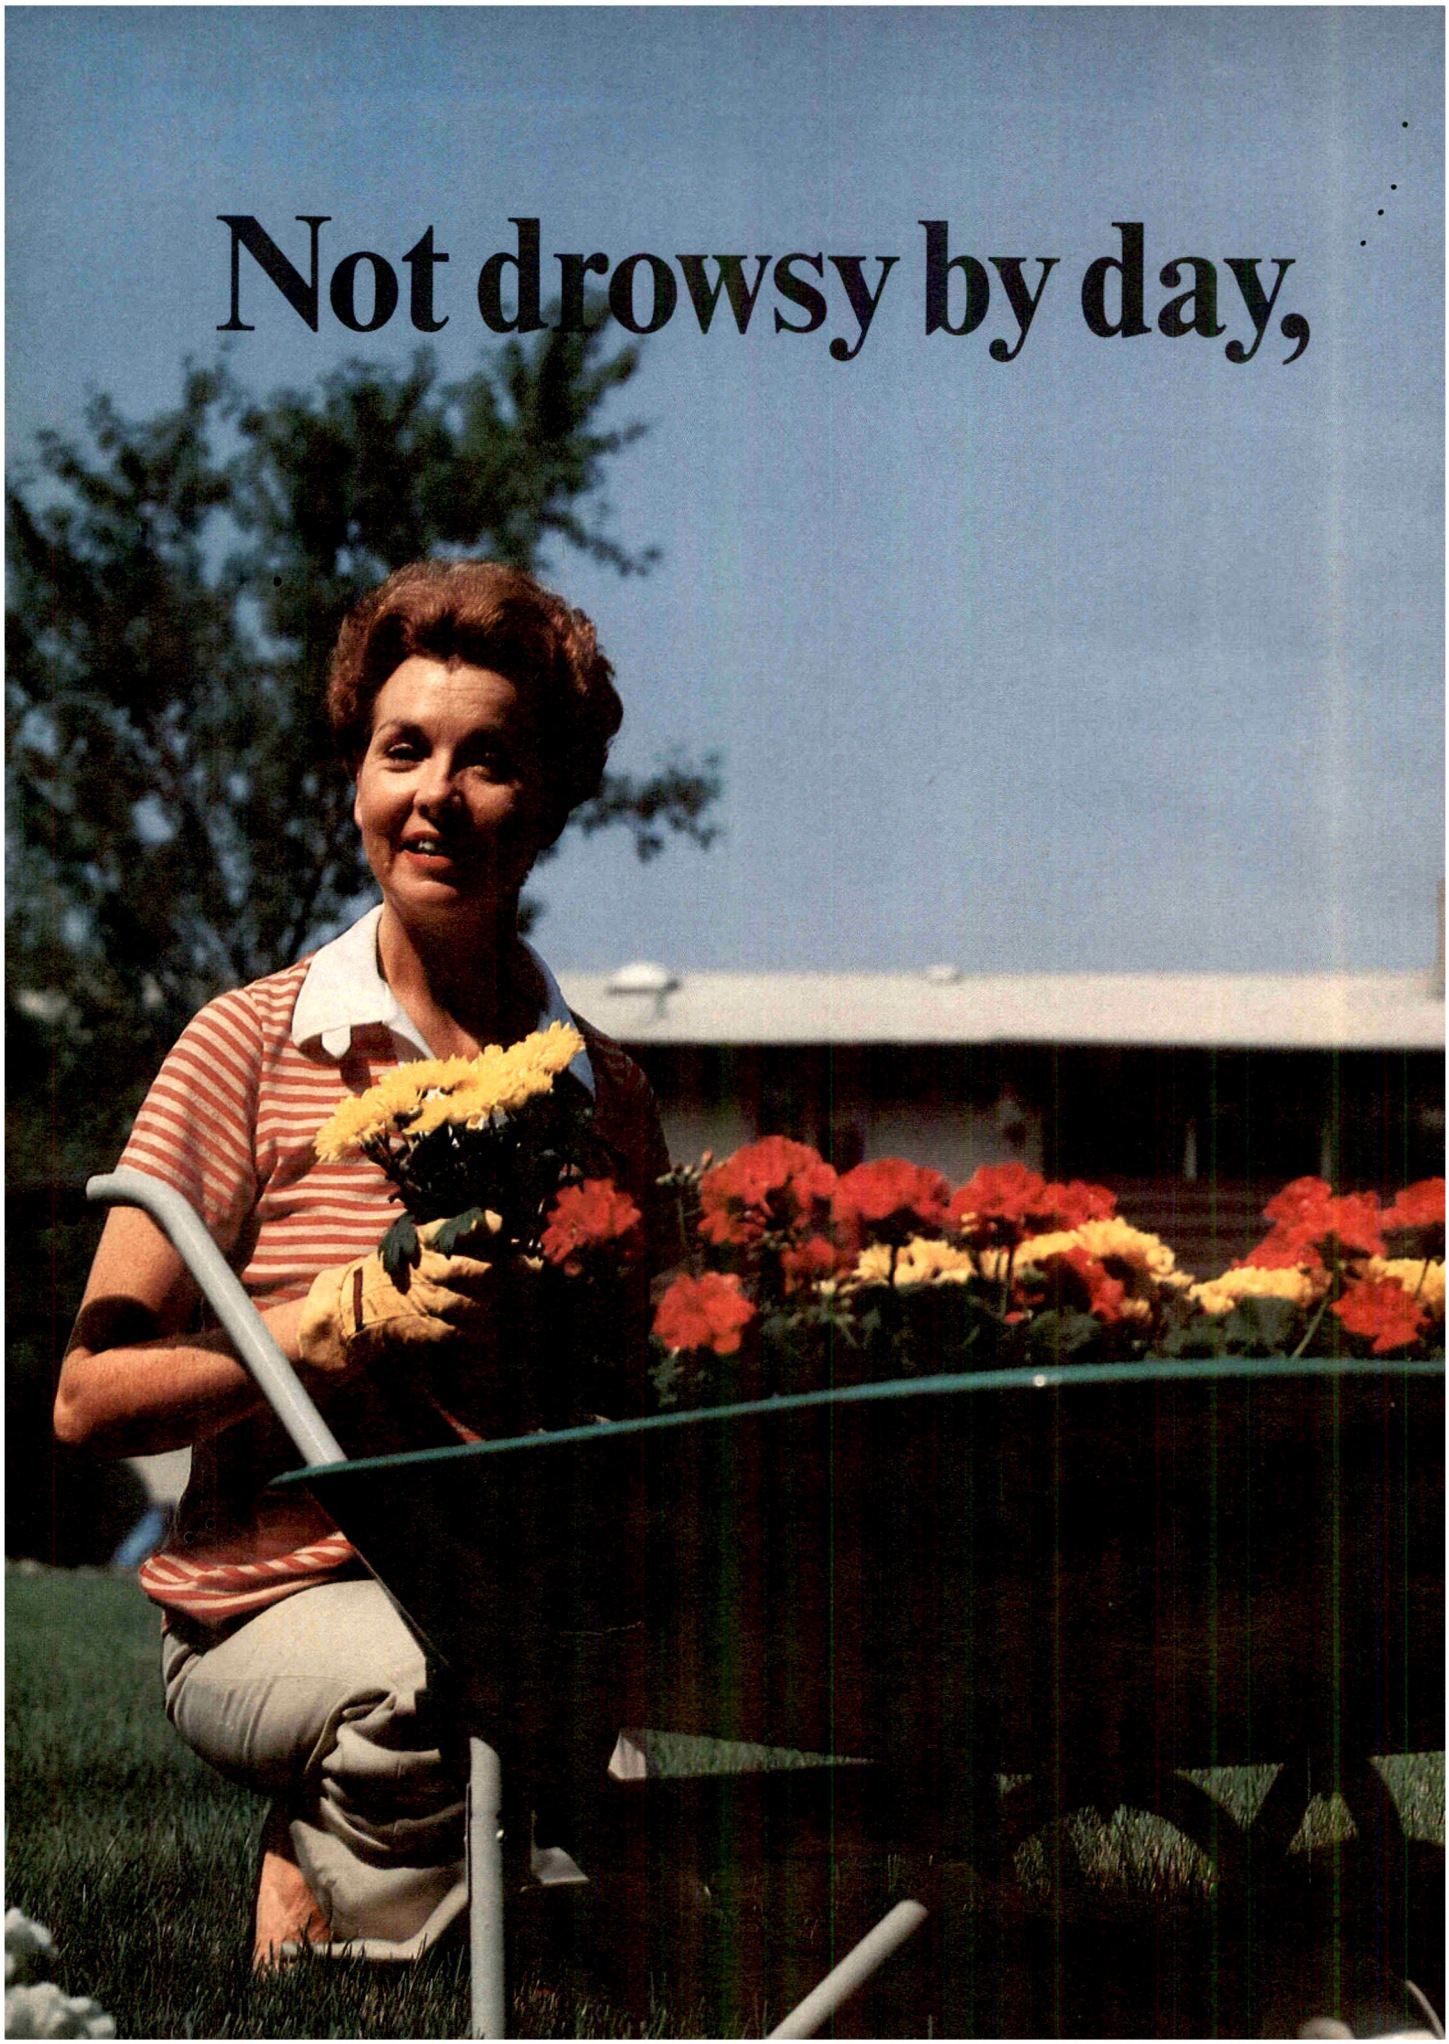
Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.



Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Supplied: *Scored Tablets:* 10, 25, 50, 75, 100, 150 mg.

Not drowsy by day,

yet anxiety controlled

Troublesome drowsiness uncommon

Tranxene lets you manage anxiety in most patients without problem sedation. Any initial drowsiness is usually transient.

Calming without impairment

Patients not oversedated can function better on the job* or at home. By avoiding excessive sedation, Tranxene helps you calm patients without compromising their capacities.
